Prehistoric people all over the world twisted fibers from animals or plants into cordage to bind objects together, knot fishnets, sew skins, and string beads. In many different locations, they looped or interlaced the cordage into fabrics for both utilitarian and decorative purposes. They incorporated designs within the fabric construction or decorated the surface with embroidery or pigments. When worn, these fabrics provided protection from foul weather, insects, and perhaps evil spirits. Cloth also offered wearers many possibilities to express identity and individuality.

Archaeology and linguistics provide evidence of early textile production. Early spinners in many locations developed techniques to make cordage or yarns by twisting animal hair or bundles of fibers from plant stems and leaves. They invented the spindle, a shaped stick with a weight at the larger end, to twist the fibers uniformly and store the spun yarn. Archaeologists seldom find spindle sticks, but often clay or stone weights have survived. Spinners in many countries still hand-spin yarns with a spindle, although some twist long plant fibers into yarn by rolling them on their bare thighs as their ancestors did.

Looms

Early people found a number of ways to arrange the spun yarns into fabric. The earliest extant examples, which date from around 6000 BCE came from a cave in present-day Israel at Nahal Hemar and archaeological excavations in Turkey at Catal Huyuk. The fabrics from these and other early sites contain fibers, like flax, from plant stems. Mesopotamian weavers along

Embroidery from Bulgaria. University of Rhode Island Historic Textile and Costume Collection, Whitlock Collection 1962.99.293.

the Tigris and Euphrates Rivers wove flax fabrics on horizontal looms. Wall paintings in tombs and three-dimensional funerary models also show Egyptians controlling stiff flax yarns on a horizontal ground loom. Basically this loom had two wooden beams spaced apart with yarns wrapped back and forth between the two beams, which were held in place by pegs beaten into the ground. This set of yarns is called the warp. The Egyptians interlaced another yarn over and under the tightly stretched warp yarns to produce a woven fabric. This intersecting set of crosswise yarns is called the weft. The width and length of the loom determined the size of the fabric. Plant fibers contain mostly cellulose, which does not dye easily, so Egyptians most often used undyed linens. They showed wealth and prestige by the fineness of the yarns and the whiteness of the fabric.

Early weavers north of the Mediterranean developed a vertical loom by suspending the warp yarns from a horizontal beam held by upright supports on either side. The warp yarns hung down from the beam. To provide order and tension, the weavers tied the lower ends of the warps to clay or stone weights. The weaver then interlaced the weft yarns beginning at the top of this warp-weighted loom. Archaeologists have found loom weights dating as early as Neolithic times in Crete, Greece, Switzerland, Hungary, Romania, Bulgaria, and Yugoslavia. Discovering a row of weights between two postholes provides clear evidence that people wove on vertical looms even when no yarn or fabric remains.

Figurines, wall paintings, pendants, and extant textiles from Egypt to China show the development of other types of looms. Most often the spinners and weavers depicted are women, who could combine these tasks with childcare. Over time in many locations, women produced textiles for domestic use; men became more involved when the cloth had potential for trade. Textiles have been a major trade commodity since ancient times, making a significant contribution to the economy of many areas.

Fibers

As sheep became domesticated around 4000 BCE, weavers produced fabrics containing wool yarns. Sumerian cuneiform tablets recorded information about sheep breeds. Wool is a protein fiber and is easily dyed, and Mesopotamian figures and wall paintings show colorful fabric patterns. Wool had limited use by pharonic Egyptians, but in the New Kingdom, they wove hieroglyphic designs in linen fabrics. The tomb of Thutmose IV contained examples of this tapestry weaving with weft yarns woven in only where their color is needed. They are tightly packed, obscuring the warp yarns. Later Egyptian Christian Coptic weavers expertly used this discontinuous weft-faced tapestry weave to create pictorial textiles. The Coptic influence is particularly obvious in surviving Syrian, Byzantine, and Persian textiles. Far Eastern weavers also produced tapestry and figured weaves, but they used different fibers.

Spinners in Tibet and China spun fibers from the stems of hemp plants. People also cultivated hemp (*Cannabis*) in Europe, but whether they used it for cordage or narcotic smoke is undetermined. Wild silkworm grew many places in Europe and Asia, but the moths cut through the cocoons damaging the fine filaments they had spun and leaving very short fibers that made yarn construction difficult. In the production of cultivated silk from *Bombyx mori* moths, the Chinese killed the moths before they could harm the filaments in the cocoons. They unwound many yards of filament from undamaged cocoons. Raising silkworms and their food source, mulberry leaves, is a

This series of drawings shows the variety of implements used over time and across cultures to twist fibers: (1) wooden peg; (2) silk winder (China); (3) spindle with whorl (Native Americans of British Columbia); (4) spindle (Mesoamerica); (5) spindle (Peru); (6) spindle for yak wool (Tibet); (7) spindle (Tibet); (8) simple spinning wheel; (9) early machine spindle (Finland); (10) flywheel spindle (China); (11) simple cotton and wool spinning wheel; (12) saxon spindle of a spinning wheel; (13) spindle commonly used on nineteenth-century cotton-spinning machines (United States).

very labor-intensive enterprise; the process is called sericulture.

The trade of colorful, patterned silk fabrics expanded westward by the late fifth century BCE, and trade routes developed into the renowned Silk Roads. The Chinese traded their silk fabrics but not their production secrets, although by the sixth century CE weavers in the Byzantine Empire were producing *Bombyx mori* silk textiles that all of Europe envied. Mosaics in Ravenna, Italy, show that lavish patterned fabrics were worn in the court of Emperor Justinian and Empress Theodora.

The other natural fiber that clothed East and West, royalty and peasant, male and female was cotton.

Originating in the Indus Valley by the third millennium BCE, cotton is the seed-hair fiber of a bush or tree (*Gossypium*). Like they did with silk, traders took cotton fabrics westward, and archaeologists have found examples at Egyptian and Mesopotamian sites. A number of classical writers described a plant on which “wool” grew and explained that gardeners chose cotton plants because they have blossoms of two different colors, depending on their maturity. Cotton grows in a variety of colors and is easier to dye than flax. Indian dyers perfected the art of coloring cotton. Beginning earlier than 2000 BCE, they made dyes that were colorfast by using mordants, metallic salts that minimize the fading of dyes by light or

laundering. Textile workers in other early civilizations shared the knowledge of mordants, most often using iron and aluminum salts.

Dyes

A significant trade of dyestuffs occurred along the Silk Roads and many other Old World routes. Coloring wool, silk, and cotton yarns and fabrics made them more valuable economically. Dyers played a major role in textile production, although they and their dye pots often had to exist on the fringes of settlements because the fermentation required for plant dyes as well as the use of urine and dung in the dyeing and printing processes gave off unpleasant odors. Early plant dyes included madder—orange-red to purple, depending on the mordant; indigo—blue; safflower—red or yellow; saffron—yellow; and weld—yellow. Like mulberry trees left from futile efforts at sericulture, madder and indigo plants, once a valuable commodity, now grow wild in many places.

Two animal dyes that produced vibrant reds came from a Mediterranean sea snail and a female shield louse that grew on trees. The Minoans of Crete probably perfected and certainly distributed the production of dye from the sea snails around the Mediterranean, although the Phoenicians are given credit for this dye, which is called Tyrian purple. The most expensive ancient dye, it is the color associated with emperors and royal courts. Kermes, the dye from the

shield louse, excelled in dyeing silk and wool. Central and South American dyers also used two similar dyes. They perfected the process of dyeing with the color from a small sac in sea snails and from a louse that lives on cactus plants. The latter, cochineal, replaced kermes and became one of the most valuable New World exports until synthetic dyes began to replace natural dyes in the last half of the nineteenth century.

Historically the dyeing process has not been as simple as dunking a piece of fabric into a pot of dye. Sun-bleaching fabrics to reduce the natural off-white colors required time and space. Dyes and mordants needed preparation, and the multistep dyeing process took days to complete. Dyers were among the earliest chemists, the earliest herbal doctors, and the earliest artists. They colored not only pieces of cloth but also skeins of yarn, which were then woven or braided into colorful patterns.

Patterned Fabrics

Many cultures have produced patterned fabrics for centuries by applying a resist in chosen areas to prevent dye absorption. Resists can be wound around yarns or fixed to a fabric. The Indonesian word for patterned fabrics woven of yarns that have been wrapped in sections to prevent dye penetration is *ikat*. Asian, African, and Guatemalan ikats are internationally fashionable today. Japanese dyers produce a very marketable product called *shibori*, an expertly patterned tie-dyed cloth. African dyers create large tie-dye designs, popular in T-shirts

Illustration of a murex shell, the source of a red-purple dye first made by Phoenicians. University of Toronto Wenceslaus Hollar Digital Collection.

today. Wax or paste resists paint. When blocked onto a cloth before dyeing, it produces a patterned fabric called by the Indonesian word *batik*. Indonesians traditionally use wax to make their batiks; Africans use cassava paste while Japanese make a rice paste. In the eighteenth century, resist pastes included chemicals that prevented a dye from fixing to a fabric. Popular indigo-resist prints in colonial America had large floral patterns influenced by the imported Indian calicoes.

A patterned fabric, even a plaid, offers marketable variations. From the earliest times, weavers devised methods of raising sets of warp yarns before inserting a weft yarn between the warps on a loom. When the weaver raised every other warp yarn, inserted a weft yarn across the width of the fabric, raised the alternate set of warps, and laid in another weft yarn, she produced a plain weave. By varying the pattern in which she raised each warp, she made other weave structures such as twills. The earliest hand-operated mechanism for selectively raising warp yarns was a string that encircled alternate warps connecting them to a rod that could pull them up away from the other set of yarns. The term for the string loops controlling the warp yarns is *heddles*. Over time, improvements to this use of heddles allowed weavers to construct fabrics with complex patterns.

The loom with the most complicated control over warp patterning was developed in the Middle East and Far East, although the Chinese often receive credit for it. The operation of this loom, called a *drawloom*, required two people: one controlled the frames or

harnesses that held the heddles to make a plain-weave base structure and inserted the weft yarns; the other sat above the loom to control the patterning warps. This second person was often a child; child labor has been prevalent worldwide in the textile industry—in homes, workshops, and mills.

Tapestry-woven fabrics, such as cashmere shawls from Kashmir, are very labor intensive and cannot be made by machines. Weaving mechanically-controlled patterns required less time than tapestry weaving and produced a very marketable product, particularly if made of silk. For a thousand years, Chinese, Japanese, Syrian, Byzantine, and Persian workshops produced exotic figured silks on variations of the drawloom. Competition from Palermo, Sicily, and Lucca, Italy, by the thirteenth century introduced fabrics that evolved into the luxurious velvets of the Italian Renaissance from Florence and other Italian city-states. Many of these fabrics are portrayed in fifteenth-century paintings and tapestries.

The Italians dominated figured-silk production through the sixteenth century, when instead of velvets, fashionable silks had patterns created by colored supplementary weft yarns. Under the guidance of Jean-Baptist Colbert, finance minister under Louis XIV, drawloom weaving in Lyon expanded. By the eighteenth century, Lyon's damasks and brocaded

fabrics surpassed Italian production, with some competition from weavers in Spitalfields outside of London. Many Spitalfields textile workers had fled persecution after the revocation of the Edict of Nantes in France, and the demise of textile production in Palermo, Spain, and Flanders was also the result of worker migration caused by political unrest and religious persecution.

Jacquard attachments on looms, a nineteenth century English invention, revolutionized figured-silk weaving, as well as the production of carpets, imitation Kashmir shawls, coverlets, knits, and machine-made laces. Lyon apartment houses with excessively tall ceilings on the top floors reflect the height and light requirements of these looms. This early computerized system used a series of punched cards that determined which warp yarns were raised to create a pattern. This basic system provides control for looms, lace, and knitting machines today.

Jacquard's invention also affected the production of lace, first made by hand in the sixteenth century. Like figured silks, bobbin and needle laces reflected conspicuous consumption by the wealthy. The English development of machines to make knits (sixteenth century) and fine net (late eighteenth century) came before more complicated equipment that imitated handmade lace. Leavers lace machines with Jacquard attachments made the best imitations and still do today in England and France. Raschel knitting

machines make the least expensive modern laces, which are not as durable as other laces because of their looped construction.

Printed Cottons

Another fabric became as valuable as lace and patterned-silk cloth during the seventeenth century. Brightly painted and printed cottons from India appealed to Europeans, and various Western trade companies set up the production of these calicoes or chintzes in East India. To obtain a share of the profits being made on the Indian prints, entrepreneurs in England and France began printing imported cotton fabric. The popularity of the imported and

domestically printed calicoes forced silk and wool producers to seek legislative restraints on the importation, local production, and use of the prints. After the bans were lifted in the mid-eighteenth century, printers, having perfected the use of mordants, sold many yards of block-printed cottons to a public whose desire had not been abated by the legislation.

Laws passed to govern consumer expenditures, called sumptuary laws, have seldom been effective, especially in regulating printed cottons, lace, and figured silks. Whether to protect local production, as in this case, to maintain social order by limiting consumption based on income, or to limit worldly excesses as determined by religious groups, sumptuary laws often fostered the development of illegal methods for consumers to obtain a product.

Christophe-Philippe Oberkampf of Jouy near Paris was the most successful early calico printer. Fast dyes and well-cut blocks brought his manufactory fame and fortune. He was one of the printers in the latter eighteenth century who experimented with faster methods of printing. The result was printing cloth with an engraved copper plate on which the design was incised into the metal surface. Copperplate printing produced large-scale monochromatic patterns with very fine lines, which were not possible with wood blocks. Ever-seeking to increase production, inventors

finally perfected an engraved copper cylinder printing machine through which fabric moved continuously. By the 1820s European and American shops produced printed cottons at price levels all could afford. Inventions by Englishmen John Kay (1733), James Hargreaves (1767), Richard Arkwright (1770s), and Samuel Crompton (1779) greatly increased the production of spun cotton yarn in England. Two Americans also made significant contributions. Eli Whitney's 1793 cotton gin made large-scale cotton production economically feasible. Samuel Slater, who had worked for Arkwright, partnered with two Providence, Rhode Island, merchants and set up a cotton spinning factory in Pawtucket. This manufactory, now the Slater Mill Historic Site, was the beginning of the Industrial Revolution in America.

The Nineteenth Century and After

By the beginning of the nineteenth century, spinning was no longer the rate-determining step in cloth production. Spinning mills in England and southern New England had thousands of spindles. With the perfection of water-powered looms after 1815 and cylinder printing in the twenties, printed cotton cloth that had been available only to the rich in the previous century sold for as little as ten cents per yard. Hand-production of cloth diminished significantly in western Europe and the United States. Dye technology also kept pace with other advancements, the most significant being the discovery in 1856 by William Perkin of mauve, the first synthetic dye. By the end of the century, most classes of dyes recognized today had been developed. Cylinder-printing technology changed little after the mid-nineteenth century and remained the backbone of the industry until rotary-screen printing took over in the 1990s.

An additional change in the 150 years of printing with dyes also occurred then. Improvements in formulations to print pigments that are insoluble in water increased the amount of pigment printing significantly. In the twenty-first century, rotary screen-printing with pigments is economically and environmentally expedient.

Work on good prose has three steps: a musical stage when it is composed, an architectonic one when it is built, and a textile one when it is woven. • **Walter Benjamin (1892–1940)**

The textile world changed irrevocably around 1910 with the commercial production of a filament regenerated from cellulose that came to be known as rayon. With improvements in the strength of rayon filaments and the introduction of acetate in the mid 1920s, the quest for an inexpensive silk-like fiber was accomplished. In the late 1930s, the accidental discovery of nylon led to the first synthetic fiber, which played a significant role in World War II. Polyester in the early 1950s, followed by wrinkle-resistant finishes on cotton, introduced the “wash-and-wear” era. A succession of new fibers, dyes to color them, and finishes to alter their properties continued to invigorate the textile market. New polymers and finishes offer elasticity, superior strength, antimicrobial properties, ultraviolet-light protection, and flame, soil, water, and impact resistance. The future is bright for consumer products and also new applications in the fields of medicine, electronics, aeronautics, and geotextiles.

Textiles have influenced economics, technology, art, religion, government, customs, and many other human endeavors. The production, design, and use of textiles are also a mirror held up to history.

Thomas Aquinas, Saint

(c. 1225–1274)

ITALIAN PHILOSOPHER AND THEOLOGIAN

Saint Thomas Aquinas represents the culmination of philosophical and theological achievement during the European Middle Ages, and his influence on subsequent generations of Western philosophers and Christian theologians has been profound.

The Italian philosopher and theologian Saint Thomas Aquinas (c. 1225–1274) proved a powerful and influential advocate of the philosophy of the Greek philosopher Aristotle. He was the author of what remains the most comprehensive effort at reconciling reason and religious faith ever attempted by a Catholic thinker.

The son of Count Landulf of Aquino, Thomas was a member of the south Italian nobility. Born at Roccasecca, between Rome and Naples, he received his preliminary education at the nearby monastery of Monte Cassino. In 1239 Thomas's parents sent him to the University of Naples, where he first engaged in intensive study of Aristotle under the scholar Peter of Ireland. During his years at Naples, Thomas made two important decisions: to devote the rest of his life to philosophy and theology and to become a Dominican friar. The two decisions were related because Dominicans were already among the leading scholars of the day. When Thomas became a friar in 1244 he received permission to leave Naples for Paris to study under the renowned Dominican philosopher and scientist Albert the Great (c. 1195–1280).

This move was opposed by his family, who intended for him to become a bishop or the abbot of a prominent monastery. Abducted by his family as he was traveling northward through Italy, he was held

captive at Roccasecca for a year before being allowed to proceed on his chosen path.

Thomas studied under Albert the Great at both Paris and Cologne, Germany, where Albert relocated in 1248 to establish a Dominican *studium generale*, a college for study of the liberal arts. Thomas served as one of his assistants, giving introductory lectures on biblical interpretation. In 1252, his academic apprenticeship completed, Thomas returned to Paris to take up the position of lecturer on the Bible and the *Sentences* of the Italian theologian Peter Lombard (c. 1095–1161), the core textbook of the theology curriculum. He also began to publish his own work and in 1256 was appointed to the position of master of theology, the highest title attainable in the academic hierarchy.

In 1259 Thomas traveled to Italy and remained through 1268, lecturing at Dominican convents and colleges in Naples, Orvieto, and Rome. He frequently attended the papal court, providing his services as preacher and liturgist. He returned to Paris at the height of his reputation but soon found himself embroiled in a major controversy over the proper relationship of philosophy and theology.

Thomas's first major book, a commentary on Lombard's *Sentences*, contains more than two thousand references to the works of Aristotle. Already in his early days as a teacher he had defined his intellectual project: to establish the proper relationship between philosophy and theology. In this pursuit he made use of not only the works of Christian theologians and ancient Greek and Roman thinkers, but also the works of Muslim and Jewish philosophers such as Ibn Sina (980–1037), Ibn Rushd (1126–1198), and

The highest manifestation of life consists in this: that a being governs its own actions. A thing which is always subject to the direction of another is somewhat of a dead thing. • **Saint Thomas Aquinas (1225–1274)**

**Vittore Carpaccio,
St. Thomas of Aquinas
in Glory between
St. Mark and St. Louis
of Toulouse (1507).
Tempera on canvas.
Staatsgalerie, Germany.**

Ibn Gabirol (1021–1058). Thomas argued that both philosophy and faith are necessary to a true pursuit of theology because logical argumentation leads to a more precise and complete knowledge of religious belief. Thomas further held that, even without faith in Christian revelation, the human mind can use rational analysis of observations made through the five senses to attain an incomplete but still extensive

understanding of the being of God and the nature of the rational laws governing the created universe.

While Thomas was in Italy, a group of scholars in Paris called the “Averroists” (followers of Ibn Rushd) were promulgating the position that the truths of philosophy and the truths of religion are equally true, but separate and distinct, because philosophical knowledge derives from rational analysis of human

experience alone, whereas theological knowledge derives exclusively from divine revelation. The bishop of Paris, Stephen Tempier, condemned the position of the Averroists in 1270. Conservative critics associated Thomas with the Averroists because of his devotion to Aristotle, and he had to expend much energy in his final years to carefully distinguish his position from theirs.

In 1272 the Dominicans sent Thomas to Naples to set up a new *studium generale*, but at this point his health began to weaken. He died at the Cistercian monastery of Fossanova while on his way from Naples to Lyons to attend a church council summoned by the pope.

The principal writings of Thomas Aquinas include the *Disputed Questions* (1256–1272); the *Summa contra gentiles* (1259–1265), which provides a detailed defense of the philosophical validity of the Christian faith; and the *Summa theologiae* (begun in 1268 but unfinished at Thomas's death), which comprehensively synthesizes Thomas's rational investigation and logical demonstration of Catholic doctrine. When Tempier condemned the Averroists a second time in 1277, he explicitly included condemnations of several teachings from these works. However, Thomas had many posthumous supporters, including Albert the Great and the Italian poet Dante, who assigned him a privileged place in paradise. Pope John XXII had Thomas canonized in 1323. During the sixteenth century Thomas's *Summa theologiae* replaced Peter

Lombard's *Sentences* as the standard textbook in the theology curriculum of European universities, where his work remained influential well into the 1600s. Thomism has enjoyed a revival since the late nineteenth century, thanks in part to a papal bull (decree) of 1879 encouraging study of Thomas's work, and his brilliant and rigorous application of Aristotelian arguments retains considerable interest for twenty-first-century philosophers.

Thucydides

(D. C. 401 BCE)
GREEK HISTORIAN

Among ancient historians, Thucydides was the most insightful. He analyzed the effect of the Peloponnesian War (432–404 BCE) on Greek society with apparent detachment and amazing precision, but his cool tone belied a love of Athens and dismay at its defeat. Thucydides wrote his narrative prose in a clear, austere style but is famous for including highly rhetorical set speeches.

The Greek historian Thucydides, and the history he wrote of the war between the Athenians and Spartans in the fifth century BCE, influenced not just the historians from the Greco-Roman world who were to follow him, but also the scholars of the nineteenth century such as Leopold von Ranke (1795–1886), laying the foundations for the modern professional study of history based on the principles of empiricism.

We know very little about Thucydides that he does not tell us himself. He states that he began work on his history when the war started. Although he refers to the end of the war, Thucydides did not live to complete his history. The narrative of the text, known today as *The Peloponnesian War*, breaks off in the middle of 411 BCE, which led ancient biographers to speculate that Thucydides died a sudden death. Most scholars conclude that he died around 401 BCE, though there is disputed evidence that he was still working on his history as late as 397 BCE. His date of birth is conjectural too. Pamphila tells us that at the start of the Peloponnesian War Thucydides was forty, and this is probably a fair guess, based upon his own remarks. Thucydides asserts that he was old enough to follow the course of the entire war and that he was elected as a general by the Athenians for a campaign

in Thrace (in 424 BCE), but was exiled after failing to relieve the city of Amphipolis. He held rights to gold mines in the Thraceward area and was well respected there. He caught but survived the plague of 430–426 BCE, which he described in great detail. His father's name was Olorus and he came from the deme (smallest political unit in Athens, used to identify citizens) Halimous. Marcellinus (who wrote a biography of Thucydides) says that Thucydides's mother's name was Hegesipyle; the name of his father is identical with that of a Thracian prince whose daughter, also named Hegesipyle, married an important Athenian aristocrat named Miltiades. Thucydides was thus related to important members of the Thracian and Athenian aristocracies, including his Athenian namesake Thucydides, the son of Melesias. Plutarch tells us that Thucydides' tomb was in the Athenian suburb of Koile Meletides, next to those of Miltiades and Cimon's sister Elpinice. Thucydides had one son that we know of, named Timotheus.

The Peloponnesian War is structured chronologically, with each year of the war described by summer and winter. Since Hellenistic times, the work has been divided into eight books (though in antiquity other divisions were made, including division into thirteen books). Book 1 includes the Archaeology, a brief survey of Greek history down to the Persian wars, the Pentecontaetia, a brief outline of events from the end of the Persian wars (described by Herodotus) to the start of the Peloponnesian War, and a lengthy introduction on the causes of the war. Books 2–4 describe the first ten years of the war (known as the Archidamian War). In Book 5 are the Peace of Nicias, the Mantinean War, and the subjugation of Melos (which includes the Melian Dialogue). Books

The secret of Happiness is Freedom, and the secret of Freedom, Courage. • **Thucydides (460–404 BCE)**

6–7 describe the Sicilian campaign and the renewal of hostilities in Attica, and in Book 8 the Ionian War and the revolt of many of Athens's allies are described. The narrative of the Peloponnesian War was completed by Xenophon, who, in the *Hellenica*, takes up his account at the exact point where that of Thucydides finishes.

Thucydides wrote his narrative prose in a clear, austere style. His historical methodology was innovative, and he drew a distinction between his research methods and those of his predecessors, criticizing Hellanicus by name, and by implication, Herodotus. He tells us that he took great care to ascertain the truth about events by finding reliable witnesses, did not even rely on his own observations, and took into account just how unreliable or partisan his witnesses may have been. He also declares that he has designed his history for posterity, not just for the pleasure of the listener (in his day histories were read aloud to an audience) or to win a particular competition.

Thucydides is famous for the set speeches that he included in his history. These are highly rhetorical, making use of complex abstract expressions and antitheses that often obscure their meaning. Here we see the results of his training under Antiphon, with the rhetoric also owing a great deal to the influence of the sophist Gorgias. It has been argued that these speeches are Thucydides' own free compositions, based upon what he deemed appropriate for the speakers to say in the circumstances. Thucydides himself claims that they were based on what had actually been said, while paradoxically admitting that he made each speaker say what he himself thought that speaker ought to have said.

Bust of Thucydides, historian and ancient Greek general. The Royal Ontario Museum.

Thucydides focused his history on war and politics—establishing these as first and foremost the subject for history. In describing the suffering caused by war and the way in which war destroyed the morals of a society, however, Thucydides moved from narrative of the particular to a general exploration of human nature that makes his history an invaluable possession for all time.

Timber

Timber, or lumber, is wood that is used in any of its stages—from felling through to processing—in the production of construction materials, or as pulp for paper. Timber has been a resource around the world for many centuries in the craft and construct of all manner of objects and utensils, from dwellings to ships to tables to toothpicks.

Since the Neolithic revolution, timber, with its many uses, has been an important commodity in the development of social life. Throughout human history from at least 3000 BCE onward, available forests have been used to meet the needs of an evolving world. Starting from the early urban communities, such as Egypt, Mesopotamia, and Harappa, timber has been a constant feature of economic life. Timber in its many forms has been used as a source of fuel and as a basic material for building construction, shipping, and for storage purposes, such as barrels). In addition to these uses, timber was important to other aspects of human activity, such as in manufacturing and for the extraction of other resources such as coal and ore (timber beams were used in shoring up mine shafts). The level of timber utilization grew in proportion to increases in urbanization, commerce, and population. The increasing size of urbanized communities and growth in population often led to the need to transport resources to feed the growing population centers of the ancient world. Shipping was the normal mode of transportation of these resources. With growing levels of trade, the increase in maritime shipping resulted in further timber consumption. Exuberant lifestyles also developed, leading to the construction of extravagant buildings, such as palaces

and temples, which often required timber for their construction.

These tendencies were pronounced as long as 4,500 years ago. In the riverine valleys of Mesopotamia and the Indus, the Mesopotamians and the Harappans deforested their own hills and mountains, and conducted military campaigns and trade relations with their neighbors to secure a regular wood supply in order to meet their economic needs. The Egyptians, for example, sought timber in neighboring areas of Lebanon and parts of the Syrian coast.

Timber utilization on a similar scale also was practiced in other parts of the world. About 2500 BCE in

Cutting timber in Washington State, 1898. New York Public Library.

northern China around the Hwang Ho river basin and in Southeast Asia timber was sought to meet socioeconomic needs. The use of wood intensified as the urbanization process progressed globally, with hinterland areas supplying the wood needs of the more economically transformed civilizations, empires, and nation-states. During different time periods, certain areas of the globe were effectively the wood yards of other regions. For example, the North American forests and those of the Baltic shores provided the timber supply for northwestern Europe in the mid-seventeenth century. By the late twentieth century, parts of Africa, Asia, Latin America, northern Europe, and Russia became the main timber sources.

With the advent of agriculture and the urban revolution, deforestation has been a constant feature for at least the last 5,000 to 6,000 years. It is literally as old as the hills. This level of deforestation reached epic proportions by the end of the twentieth century. The size of the world's forests has shrunk by nearly half from 6 billion hectares 8,000 years ago to 3.6 billion hectares presently. According to the World Commission on Forests and Sustainable Development, forests have virtually disappeared in twenty-five countries, eighteen others have lost more than 90 percent of

their forests, and eleven countries have lost around 90 percent. In an attempt to slow deforestation and to help reduce the environmental impact of cutting trees for timber, some states and timber producers have planted special plantations of fast-growing trees specifically so they can be cut for timber. When the trees are felled, new saplings are planted in endeavor to make plantation timber environmentally sustainable. Selective logging of mature trees in a forest of mixed age is another method of combating deforestation.

There is common agreement that deforestation has consequences for human communities. Negative outcomes such as soil erosion and the climatic changes that we are witnessing also occurred in the past. The “modern” problems of soil erosion leading to flooding and silting of rivers and canals also occurred in early Mesopotamia and had a severe impact on economic production. The effects of soil erosion and its consequences also appeared in northwestern India, China, Mycenaean Greece, and Minoan Crete, engendering pressures on these societies and civilizations. Deforestation also has engendered climate changes and precipitation. The removal of the forests cools the lower atmosphere while warming the ground surface. The reduction of evapotranspiration

An illustration of Aramaic bas-relief sculpture from Assyria depicts ships transporting timber, both aboard and towed by rope. New York Public Library.

causes aridity. Forest loss also means that there is a reduction in carbon sequestration as the trees fix carbon and metabolize carbon compounds. This loss exacerbates the process of global warming. Recent studies have suggested that this process has been an ongoing for at least 6,000 years following the spread of agriculture that had facilitated the removal of the forests.

Time, Conceptions of

Appreciating the diversity and evolution of cultural and scientific views of time—linear time and cyclical time—requires a wide-ranging journey through history to consider how diverse cultures conceived of and measured time. The interplay between the practical ability to measure time with clocks and the abstract concept of time itself is major theme of this article.

We all live in time, but we almost never ask ourselves about its nature. Moreover, people in the industrialized West are generally unaware that their typical understanding of time embodies a set of assumptions (for example, a linear “flow”) that have changed throughout history, are not shared by all cultures, and are even fundamentally at odds with current science.

Cultural Understandings of Time

There are as many conceptions of time as there have been human cultures, but it is common to identify two kinds of time. First, there is linear time, a steady progression from the distant past to the far future. For some, this view is based on Christianity, in which time has both a beginning at Creation and an end at Christ’s second coming; for others, it is based on science, assuming a steady evolution both of knowledge and of life itself. Second, there is cyclical time, where the recurring motions of a clock or the stars do not merely mark off constant intervals, but indicate a repetition of human experience and history. A division between linear and cyclical is nevertheless overly simplistic, just as it would be to identify the

linear with the West and the cyclical with the East. There is instead a continuum of emphasis, so that for example early Chinese writings identify both *ji*, the linear succession from ancestors to descendants, and *li*, repetitive cycles of death and rebirth in the natural world.

Both linear and cyclical time can be seen in any calendar, which reveals not merely the calculations by which a society numbers days and years but also something of how that society understands time itself. For example, the development of the Gregorian calendar is a fascinating thread through history, in which priorities, arguments, and human decisions are revealed in every detail: the names of the months, the date of Easter, and the contortions needed to keep synchrony with the orbit of the Earth. The Mayan calendar intricately interlocks a multitude of cycles, including the 365-day *haab* (the seasonal year) and the 260-day *tzolkin* (itself composed of overlapping cycles of 13 and 20 days), and lists auspicious and ill-fated days for a recurring round of secular and sacred tasks. Indian calendars compose an escalating hierarchy of scales in which a single day in the life of Brahma, the creator god, is equal to almost nine million human years.

Finally, we may also identify a third kind of time, common to many indigenous peoples including those of Australia, North America, and the Arctic. These cultures are often seen as timeless, sometimes on simplistic linguistic grounds. Yet their time may be strictly more intricate than clock time, incorporating a detailed understanding of natural cycles but adding social, spatial, spiritual, and even eternal dimensions.

The Value of Time

Early agrarian and seafaring communities were based on a daily and yearly round of chores governed by the land or the sea. There was little need for external or absolute time, only for the knowledge of the appropriate succession of tasks and of the cues to match this sequence to natural rhythms: sowing and harvesting or the ebb and flow of the tides. The duration of an interval was likewise reckoned not in hours, minutes, and seconds but by comparison with common experience: the time taken to boil an egg, say a prayer, or perform a bodily function—for instance a “pissing while—a somewhat arbitrary measurement” (Thompson 1991, 356).

It is often assumed that public time consciousness began with the medieval “hours” of European monastic communities. This daily cycle of liturgical offices was announced by the ringing of bells, and may have been an important influence in the development of the mechanical clock. But hours originated with the Egyptians, who first divided night and day into twelve parts each. The monks only inherited this convention

by way of the Greeks and the Romans, both of which used sundials and clepsydrae (water clocks) to order their society. Even the modern complaint against the tyranny of the clock is not new: “The gods confound the man who first found out how to distinguish hours. Confound him, too, who in this place set up a sundial, to cut and hack my days so wretchedly into small portions!” (Titus Maccius Plautus, c. 254–184 BCE).

There were three key factors in the escalation of time pressure through Western-led industrialization. The first was the development of labor as a commodity, which ascribed a new value to every hour of work for both employer and employee, and created a new distinction between work and personal time. The second was the proliferation of clocks and watches; by the end of the seventeenth century, timepieces were shifting from a luxury affordable only by the wealthy to a convenience available to all. The third factor was the rise of a work ethic which set a moral, commercial, and even theological value on industry and deprecated idleness. Benjamin Franklin most famously and succinctly stated this as “Time is money”: not only is time a currency which we choose how to

A Kłowa (Native American) pictograph calendar on bison skin. The bars and attached figures in the center form a winter count, with each representing one year, while the figures near the edges provide a history of thirty-seven months during the 1890s.

*Time present and time past / Are both perhaps present in time future / And time future contained
in time past.* • T. S. Eliot (1888–1965), from “Burnt Norton” (No. 1 of *Four Quartets*)

spend, but wasted time is unearned money. Nevertheless, one might argue even in the modern age that this sentiment enshrines a capitalist, predominantly masculine view of time, and undervalues the continuing task-oriented round of domestic daily chores often carried out by women.

From Solar Time to Coordinated Universal Time

As late as the turn of the nineteenth century, the only time that mattered was local time. Every town had its own time: solar noon, when the sun is highest, shifts around one minute later for every twelve miles moved to the west (at the latitude of London). Moreover, this apparent solar time varies through the year because of the eccentricity of the Earth’s orbit and the tilt of its axis, sometimes in front of and sometimes behind regular clock time.

The shift away from the sun as primary timekeeper began at the turn of the eighteenth century with the adoption of mean solar time (averaging out the variations of apparent solar time with a clock) and accelerated with the spread of the railways. Before rail, only mail couriers traveled far enough in a single day to encounter the variety of local times. The railway age brought the advent of rapid public travel, timetables, and telegraph cables beside the tracks, providing both motive and means for time to be standardized along the line. Railway companies disseminated their own standards, which were quickly taken up by public clocks; formal adoption of a single standard for legal purposes lagged decades behind. The situation was especially complicated in countries such as the United States, which had many competing interests and a wide geographical expanse.

We are so accustomed to time zones today that it is hard to understand the fierce debate engendered by their proposal as companies and cities fought for commercial and political supremacy. Charles Dowd, an educator from Wisconsin, proposed a zone system for U.S. railways in 1872, but it was not until 1883 that a proposal by William Allen, a U.S. senator, was finally adopted (smaller Britain had adopted

The transmigration wheel of Buddhism shows the six paths of reincarnation. All creatures travel through repetitive cycles of death and rebirth in the natural world.

Greenwich time much earlier, in 1840). Sandford Fleming, a Scottish-Canadian inventor and engineer, argued in 1876 for worldwide rationalization, setting out the key features of the system we use today. Inevitably, the same battles were fought as fiercely between nations, culminating in the Prime Meridian Conference of 1884, which adopted an international system of standard time zones, but more crucially selected Greenwich as the prime or reference meridian. It is well documented that commerce largely dictated this choice, in particular the dominance of shipping charts based on Greenwich, which harkened back to the seventeenth century, when British astronomers and clockmakers vied to solve the problem of determining longitude at sea.

In the twentieth century, ever more precise clocks began to reveal that the Earth’s rotation was not completely regular. The first atomic clocks were developed in the 1950s, and in 1967 the international definition of the second was changed so that the cesium atom is now our primary timekeeper. Coordinated Universal

Time is the modern descendant of Greenwich Mean Time, but refers instead to an international network of atomic clocks. Today we know the time without ever looking at the sun; we encounter jet lag as we fly from one time zone to another; and we know not only the time here but the time there: we know when the stock market opens in New York or in Tokyo and the difference between clocks in London and Paris.

From Absolute to Relative Time

Study of the relationship between time and motion extends at least as far back as Greek philosophy. For example, to Plato time was “the moving image” of an ideal static eternity, manifested in and even brought into being by the motion of celestial bodies. Aristotle questioned this identity, seeing time rather as a “numbering” of motion, dependent on perception of change. Augustine, drawing on this tradition, suggested that this perception implies a human observer, who by memory and expectation may circumvent the apparent fact that only the present is in any sense real.

With the invention of the mechanical clock, the regular motion of the heavens could be represented in miniature—figuratively, but also directly, as public clocks by the late fourteenth century might also elaborately display the phase of the moon or the movement of the planets. It is then only a short step to a view of the whole universe as a clockwork machine, put forward for example by Kepler and Boyle and a key feature of the seventeenth century scientific revolution. Newton, developing the views of Isaac Barrow, famously stated at the beginning of *Principia* that “absolute, true and mathematical time, of itself, and from its own nature, flows equably without relation to anything external.” Both the stars and the clock merely count off the flow of this absolute time, which may be represented geometrically by a straight timeline with each point a single instant.

Leaving aside philosophical disputes, Newton’s definition survived unchallenged for over two hundred years, until Einstein. Einstein’s theory of relativity begins with two postulates: physical laws should not

depend on any motion of the observer, and the speed of light is the same for all observers. The second jars with everyday experience: as a car accelerates away from a standstill, its speed over the ground increases but the speed of the light from its headlights does not. It also has far-reaching consequences. Imagine that you are standing in the center of a stadium, and I am running past you just as the lights are turned on. You see all the lights turn on at the same time—a little after they actually did, because their light takes time to reach you. But in this time I have moved towards one side of the stadium. I see that side turn on first, because that light travels a shorter distance to me at the same constant speed. A third person running past you in a different direction experiences events in a different order again. The profound message of relativity is that relative motion—one observer moving relative to another—unavoidably leads to relative time, with no unique, correct, or absolute order of events.

Relativity has still stranger consequences. Time passes at a slower rate for a moving observer; if one of two twins takes a rocket trip, he will be younger than his brother when he returns, and the faster he travels the less he will age. Time similarly slows as gravity increases, so that clocks tick slower on the ground than they do in orbit. These bizarre predictions of Einstein’s theory have been verified to extraordinary accuracy by experiment, and they even impact on modern life: for the Global Positioning System to provide accurate navigation, the satellite atomic clocks must be corrected for these effects.

Scales of Time

Science has revolutionized our understanding of the scale of time as well as its nature. In antiquity, anything shorter than a heartbeat was the realm of philosophy, anything longer than a lifetime that of history, religion, or myth; both were inaccessible. Authors of medieval *computus* texts (notably Bede, the Benedictine monk) speculated on the smallest part into which a day might be divided, but were principally concerned with calculating the date of Easter. At the other end of the scale, Archbishop James Ussher

What is time? Who can explain this easily and briefly? . . . Provided that no one asks me, I know. If I want to explain it to an inquirer, I do not know. • **Saint Augustine (354–430)**

of Armagh deduced around 1650 that the universe was created in 4004 BCE on Saturday 23 October at 6 P.M. Other cultures incorporated much longer epochs in their chronology, for example the Mayan and Indian cycles already noted, but these figures were largely simple mathematical progressions of shorter-scale calendars.

Today the range of time intervals open to direct study has widened dramatically. Modern technology slices time ever finer: races are timed to thousandths of a second, atomic clocks are synchronized across the globe to billionths of a second, and the fastest laser pulses open a window to timescales shorter than one femtosecond (a millionth of a billionth of a second). In the realm of “deep time,” the age of the Universe is believed to be around thirteen billion years, of the Earth around four and a half billion years, and of our hominid ancestors over seven million years (this is still much discussed as new fossils are found). These figures draw on advances in geology, palaeontology, astronomy, and cosmology, which were only refined through the nineteenth and twentieth centuries.

Personal Time

In the late nineteenth century, researchers began trying to understand the biological processes that embody our personal consciousness of time. Great progress has been made in characterizing human biological cycles, including the well-known circadian rhythms that have a period of approximately one day, and using this knowledge to advantage; for example, the effectiveness of drug treatments can vary significantly with the time of day. Cellular and physiological processes that underpin a multitude of personal “clocks” are yielding their secrets, including mechanisms for synchronizing body functions with the environment (a built-in clock) and a separate interval timer for estimating elapsed duration (a built-in stopwatch). Neurological research can identify the areas of the brain that are important for human memory, whereby both the time stamp attached to a specific event and the chronological sequence based on these time stamps can be stored and retrieved.

Nevertheless, a real understanding of human time consciousness—particularly the great variation in the rate at which we can experience the subjective passage of time—remains elusive. It is also particularly ironic that these new insights come at a time when for many life is increasingly separated from natural cycles: for example, shift work, twenty-four-hour shopping, and even air-conditioning or electric lighting all blur our link to environmental time.

The Future

The rate of improvement in our ever-advancing ability to measure time is roughly exponential. The day is the same length now as it ever was (at least, to a very good approximation), but accelerating social change makes time seem in shorter supply and consequently much more precious. Many authors argue that a kind of liberation from slavery to clock time is needed, repeating a challenge heard as early as Roman times and which has frequently recurred through history and literature since then.

Clocks underpin much of our modern infrastructure, from telecommunications to electricity distribution to electronic trading to satellite navigation. We take for granted a technical mastery over time, yet time is ultimately as much of a mystery as ever. As sociologist Michael Young (1998, 245) put it, “We can delude ourselves that we know what time is because we know what time it is.” The future of time itself will surely yield as much color and change as its past has.

Timur

(1336–1405)
TURKIC CONQUEROR

The Turkic conqueror Timur is remembered as a skilled debater, a speaker fluent in several languages, and one of the last great nomadic warriors. Timur organized notorious massacres from India to Turkey, leaving numerous towers of skulls as reminders to the conquered.

Timur-i Leng (Timur the lame), also known in English as Tamerlane or Tamburlaine, was the last of the great nomadic emperors. His detractors called him Timur-i Leng because his right arm and leg were paralyzed from arrow wounds received during a raid in his youth. During his reign, however, he was known as Emir Timur, and he engaged in a career of conquest that took him from India to Turkey and that shook the foundations of several empires.

Born near Kesh (now Shakhrisabz, in Uzbekistan), near Samarqand in 1336, Timur was the son of Tara-gai of the Barlas tribe, a tribe of Mongolian origins but thoroughly Turkic in ethnicity by Timur's lifetime. Timur began his career as a minor leader and sometimes bandit during the unrest that marked much of Central Asia during the mid-fourteen century.

With the collapse of the Chagatai khanate, a successor state of the Mongol Empire that covered most of Central Asia, new opportunities arose in the region. Timur took advantage of the situation and became the lieutenant of his brother-in-law Husain. The two gained control of Mawarannahr (Arabic for "the land between the rivers,"—the rivers being the Syr Dar'ya and Amu Dar'ya), or Transoxiana, before a falling-out pitted them against each other in 1370, with Timur emerging as the victor.

After becoming the ruler of Mawarannahr, Timur spent the following ten years consolidating his control

in the region and defending it from raids by the remnants of the Chagatai khanate in what is now Kazakhstan and Xinjiang (northwestern China). In 1380 Timur supported Toqtamysh, a prince of the Golden Horde (another successor empire to the Mongol Empire; it controlled the area of present-day Russia and Ukraine), in Toqtamysh's bid to rule the Golden Horde.

Timur leading his troops.

This Persian miniature from the *Zafarnama of Sharaf Al-Din 'Ali Yazdi* (Book of Victory), written between 1595 and 1600, depicts the defeat by Timur of the Sultan of Delhi in the winter of 1397–1398.

Not until 1383 did Timur attempt to expand his realm beyond Mawarannahr, sending his forces across the Amu Dar'ya into Persia. By 1385 Timur had incorporated the regions of Khorasan (which is now present-day northeastern Iran and surrounding areas of Afghanistan), Afghanistan, and eastern Persia (Iran) into his realm, and by 1394 the regions of Fars (present-day southwestern Iran), Iraq, Azerbaijan, Armenia, and Georgia had succumbed to his armies as well. Timur rarely established an effective administrative apparatus in his conquered territories, apparently preferring plundering territory outside of Mawarannahr to governing it effectively.

Meanwhile, Timur's protégé Toqtamys, now the ruler of the Golden Horde, decided to challenge

Timur's authority. As a descendent of Genghis Khan, Toqtamys viewed himself as the rightful ruler of all the lands that the Mongol Empire had once comprised. Toqtamys defeated Timur's generals during invasions in 1385 and 1388; Timur retaliated by invading the Russian steppes in 1391. Although Timur defeated Toqtamys and dethroned him, Toqtamys regained power and invaded Timur's empire again in 1395. Timur in turn struck back, defeating Toqtamys once and for all on the Kur River in 1395 and proceeding to break the power of the Golden Horde.

Timur did not incorporate the Golden Horde into his empire, preferring to place a puppet ruler on the throne. Not content with his victories in Persia and the Russian steppes, Timur invaded India in 1398, justifying his actions—as he did for many campaigns—on religious grounds. In the case of the destruction of the sultanate of Delhi, he justified his actions on the grounds that Sultan Mahmud Tughluq was excessively tolerant of his Hindu subjects. In the wake of the sack of Delhi, Timur's army carried an immense amount of wealth back to his capital at Samarkand.

Timur did not stay long in his capital. In 1399 he marched west, his eye on both the Mamluk sultanate (in Egypt and Syria) and the Ottoman Empire (in Anatolia, modern Turkey). Both states had either supported enemies of Timur or threatened his clients. After putting down a rebellion in Azerbaijan, Timur invaded Syria in 1401 and defeated the Mamluks, sacking Aleppo and Damascus in the process. Timur then invaded Anatolia and defeated the Ottoman army at Ankara in 1402; his capture of the Ottoman sultan Bayezid I left the Ottoman Empire in turmoil.

With his western frontier secure, Timur returned to Samarkand in 1404, where he began planning for an invasion of China (at that time ruled by the Ming dynasty). The invasion ended prematurely in 1405, when Timur died at the city of Otrar. His empire, held together primarily through the force of his will, quickly disintegrated into smaller states ruled by his sons and grandsons.

In the annals of world history, Timur is remembered most for his conquests and cruelty. He orchestrated many massacres and left numerous towers of skulls as reminders to the conquered. Although illiterate, Timur was noted for being very intelligent, an expert chess player, a fluent speaker in several languages, and well versed in the art of debate. Furthermore, Timur dramatically impacted five states. His defeat of the Ottomans made it possible for the Byzantine Empire to survive fifty years longer than it might have otherwise, as Bayezid had planned to attack Constantinople before being defeated by Timur. The defeat of the Mamluks, while not destroying them, exposed the slow decay of their once grand military might. By defeating Toqtamysh, Timur eroded the strength of the Golden Horde and accelerated the end of nomadic dominance over the principalities of Russia. Although he sacked Moscow, then a small town, Timur's defeat of Toqtamysh actually contributed to that city's rise. His destruction of Delhi, on the other hand, was the death knell for the sultanate

of Delhi. Although Timur's empire disintegrated after his death, Timur's descendants established the Mughal Empire in India, supplanting the sultanate of Delhi.

Tobacco

Tobacco is a plant in the genus *Nicotiana* that contains the addictive drug nicotine. The leaves of the tobacco plant can be processed and used for smoking, chewing, or inhaling. Originating in the Americas and introduced to Europe in the sixteenth century, people have used tobacco for centuries. It was not until the 1930s that physicians realized the health implications associated with tobacco.

The tobacco plant is a member of the family Solanaceae and the genus *Nicotiana*. It is a coarse, large-leaved perennial that grows in warm climates and rich, well-drained soils. Tobacco's defining feature for people is its nicotine, which makes up 2 to 7 percent of the leaf. In concentrated form, nicotine is used as an insecticide and drug. It acts primarily on the human autonomic nervous system and, in small doses, imparts feelings of alertness and pleasure. Nicotine is physiologically addicting, which is perhaps one of the major reasons for tobacco's global spread.

Early History

Tobacco (*Nicotiana tabacum*) was first grown by natives in the pre-Columbian Americas. It is thought to have first been cultivated in the Peruvian Andes, where it was used for medicinal and ceremonial purposes. From there it spread throughout the continent. Evidence shows that the Aztecs smoked tobacco leaves stuffed in hollow reeds and that Central and North American natives smoked thick bundles of tobacco wrapped in palm leaves and maize husks.

Because tobacco was a medium that connected the natural and supernatural worlds, shamans used large quantities of it in religious ceremonies and healing rituals. In order to alleviate certain illnesses, for example, shamans placed tobacco on patients' skin, eyes, gums, and tongue or boiled the leaves in water and fed it to patients as a liquid.

Although tobacco was introduced from Mesoamerica to North America about 200 CE, Europeans did not come into contact with it until many centuries later. Christopher Columbus became aware of tobacco when he visited the West Indies, where he had seen the Cuban natives smoking small cigars (*tabacos*) through their nostrils. He brought a few tobacco seeds and leaves with him back to Spain. At first, because tobacco was a rare commodity, smoking signified social status and wealth. Most Europeans did not get their first taste of tobacco until the mid-1500s, when travelers and diplomats like Englishman Sir Walter Raleigh and the Frenchman Jean Nicot (for whom nicotine is named) popularized its use. By the early 1600s tobacco had spread throughout most of South America, Europe, the Caribbean, and the North American colonies.

Tobacco in the American South

Tobacco soon became an important commodity in Europe but an even more important commodity for the American colonies. Virginia, Maryland, and North Carolina's eighteenth- and early nineteenth-century economies depended almost entirely on tobacco, which was harvested as a cash crop and sent to European and North American colonial markets.

Nicotiana glauca (cultivated tobacco), from *Tobacco, Its History and Associations: Including an Account of the Plant and its Manufacture; with its Modes of Use in All Ages and Countries*, by Frederick William Fairholt (1814–1866).

Indeed, tobacco was the single greatest factor in the development of the southern colonies' economic, political, and social life.

The Englishman John Rolfe, who observed local Native Americans growing different strains of tobacco, cultivated the first successful commercial crop of *Nicotiana glauca* in Virginia in 1612. In fact, the Native American princess Pocahontas was the first “poster girl” of tobacco, and her marriage to Rolfe assured that native peoples would not attack the Jamestown colony or destroy the new cash crop. By the 1620s tobacco had become Virginia's major crop.

Virginia's fledgling tobacco industry created great demands for land and labor. Because tobacco quickly depleted the land by removing nitrogen and potash

from the soil and depositing toxic elements, farmers seldom planted more than three or four crops on the same plot of land before they abandoned it to corn or wheat. Thus colonial planters constantly cleared forest to make room for more tobacco lands and began to establish large plantations deeper in the interior.

For the next two centuries, tobacco cultivation, which was labor intensive, fueled the demand for labor, particularly imported African slave labor. To start a crop, seeds were sown in beds in late spring. Plants had to be carefully weeded and cut. In early fall, ripe plants were cut and hung on pegs in a ventilated tobacco house to cure for a month or more. The leaves were then cut from the plant, tied into bundles, and shipped to England and the other colonies. At first, planters relied on indentured servants imported from England for this labor. But after 1700 tobacco plantations employing several dozen imported African slaves or more were common, and, by the 1790s, more than 650,000 slaves worked on tobacco plantations. By the time of the Civil War, the South's agricultural economy rested on the labor of more than 4 million African slaves.

By the 1830s, however, the instability of the tobacco market, combined with soil exhaustion, had created unfavorable conditions for tobacco expansion. Many farmers in the old tobacco-growing regions of Virginia, Maryland, and North Carolina shifted to other crops, and the center of tobacco cultivation moved westward. In the mid-nineteenth century, while the North experienced dramatic economic growth, the South remained primarily agrarian. Short-staple cotton replaced tobacco as the region's dominant agricultural commodity by the late 1800s.

Cigars, Cigarettes, and Cancer

Tobacco was initially cultivated for pipe smoking, tobacco chewing, and snuff dipping. Cigars became common in the early 1800s, and cigarettes became popular in the 1860s, although they had existed in crude form since the early 1600s. The spread of “Bright” tobacco, a yellow leaf grown in Virginia and

Men puff away while women hide their faces behind large hats and handkerchiefs. From *Tobacco, Its History and Associations*, by Frederick William Fairholt.

North Carolina, combined with the invention of the cigarette-making machine in the late 1880s, created new markets for cigarettes. Improvements in cultivation and processing likewise reduced the acid content in tobacco, making cigarette smoking more appealing to the masses.

The harmful health effects of tobacco were not initially known. In fact, many physicians, who looked at Native American uses of tobacco, recommended the leaf for medicinal uses. But by the early twentieth century, scientists and physicians began to address the harmful health effects of tobacco. In 1930, German researchers statistically correlated cancer and smoking. In the following decade the American Cancer Society linked smoking and lung cancer. A *Reader's Digest* article published in 1952 outlined the dangers of smoking and had tremendous impact on the smoking community. Tobacco sales subsequently declined. The tobacco industry countered claims that linked nicotine and cancer but nonetheless introduced "healthier" lines of cigarettes, including filtered

cigarettes with low-tar formulas. By the 1960s, however, the formation of the Surgeon General's Advisory Committee on Smoking and Health again threatened big tobacco by showing that the average smoker was ten times more likely to develop lung cancer than was the nonsmoker. In 2008 the World Health Organization reported that tobacco related ailments are the leading preventable cause of death worldwide, accounting for as many as 5.4 million deaths in 2004 and possibly as many as 100 million deaths throughout the twentieth century.

Since the 1960s the tobacco industry has been engaged with the government and citizens' groups in battles over the proper labeling, advertising, and sales of tobacco. In 1971 all broadcast advertising in the United States was banned, and the days when one heard a famous soprano declare, "I protect my precious voice with Lucky Strikes" ended. The first major legal challenge to the tobacco industry came in 1993, when Rose Cipollone, a smoker dying from lung cancer, filed suit against Liggett Group, claiming that the company

Cards series, number 963
(c. 1922–1939).

had failed to warn her about tobacco's health risks. She won a \$400,000 judgment against the company, but the judgment was later overturned. In 1994 the state of Mississippi filed the first of twenty-two state lawsuits seeking to recoup millions of dollars from tobacco companies for smokers' Medicaid bills.

While estimates vary, tobacco production and consumption is on the rise. World tobacco production is thought to have risen from 4.2 million tons in 1971 to an average of 6.9 million tons between 1998 and 2000. China, India, and Brazil are the top three tobacco producers; the United Nations Food and Agriculture Organization projects that world tobacco leaf production will reach 7.1 million tons in 2010.

While smoking rates have leveled or dropped slightly in the developed world, they are on the rise in the developing world, particularly those countries experiencing rapid economic growth. Of the world's estimated 1.22 billion smokers, 1 billion of them live in the developing world. In many Western countries smoking is now banned in public places such as restaurants.

Tourism

The first tourists traveled ancient lands to festivals and sites of religious or ancestral significance, their movements facilitated by the building of roads and ships. Upper-class men began to tour the world for education and scientific study in the late fifteenth century. Modern tourism, or leisure travel, developed along with more accessible and efficient means of transportation, such as railroads, steamships, automobiles, and airplanes.

Tourism is a relatively new field of study within the discipline of history. Its connection with trends in social, cultural, and economic history, however, means it is a valuable research area. Tourism is generally defined as travel outside a person's usual environment, primarily for leisure, but the term can also be applied for other purposes. Though the term "tourism" was first coined in the early nineteenth century, the activity has much deeper historical roots. Technology has facilitated changes in travel over the centuries, and, from ancient times, leisure, trade, pilgrimage, and empire have seen people travel across regions and cultures forging connections and contacts. A chronological look at the history of tourism shows its transformation over the centuries from travel only occurring out of necessity, through its association with leisure as a privilege of the upper classes, to an industry of its own in the twenty-first century.

Trade

Most sources point to the Sumerians (Babylonians) and their development of trade around 4000 BCE as the birth of travel (Goeldner and Ritchie 2009).

Initially merchants traded locally and then, after the development of ship technology, traded further afield, across the Mediterranean Sea and Indian Ocean (Casson 1994). Trade remained the major motivation for travel over the centuries with the vast trading networks of the fifteenth and sixteenth centuries. Even though this may not come under the banner of what we think of tourism today, travel through trade often saw movement across vast distances and cultures. The Silk Roads are a prime example here, as traders traveled from Europe to China over a number of different routes. From the fourth century BCE, the Silk Roads saw travel link Asia and the Mediterranean through trade, military movements, and religion. Travel was difficult and dangerous, however, and was only conducted when necessary. Trade, military, and administrative purposes were the main motivations for travel in the ancient and medieval periods, although religious festivals, pilgrimage, and other leisure travel were also evident and more of a reflection of modern tourism.

Pilgrimage

From the time of the ancient Egyptians, pilgrimages and festivals have taken travelers across borders. Tourism, as in travel for pleasure, is evident in Egypt from 1500 BCE onward (Casson 1994). The pyramids were a site of pilgrimage for Egyptians, and, even though this travel was still relatively local, it demonstrated the importance of pilgrimage as an instance of early tourism. Travel for pilgrimage is also evident in many Asian countries, particularly in China, where a culture for travel can be seen from an early period (1350–1050 BCE) when people journeyed

Map of the Silk Roads route by Ruscelli (sixteenth century). Treks along this ancient trade route, to religious festivals or pilgrimage sites, gradually gave way to travel resembling modern tourism.

to the mountains and rivers to visit their ancestral gods and spirits (Sofield and Li 1998). Travel, however, was still a disjointed experience and a difficult undertaking on treks over long distances.

The building of roads during the Roman Empire facilitated a new medium for travel. A network of about 80,500 kilometers (50,000 miles) of roads had been built by the first century BCE spreading across the empire. Roman roads allowed travel across northern Europe in Britain and Germany to southern Europe into Egypt. As a result, travel for leisure across Europe gained popularity among Romans, and the new road technology meant greater distances could be covered at a greater speed. Romans traveled to sites and monuments across the empire to sightsee at popular destinations, including the pyramids and the sites of Greece. But this trend did not last, and after the collapse of the Roman Empire and the division of Europe, roads were no longer maintained and travel once again became difficult and dangerous.

Despite this, pilgrimages continued across Europe during the medieval period with travelers crossing regions to visit shrines, churches, relics, and other sites of religious significance. Consequently, as the main sources of hospitality along the road, churches and monasteries allowed travelers to overcome the dangers of travel. There are many surviving accounts of

pilgrims' journeys and guide books with information and instruction for travelers. Pilgrimages often took travelers across borders and put them in contact with cultures they would not normally have encountered. This sometimes caused conflict, and the domination of religious travel eventually faded, giving way to travel as a search for knowledge and culture.

The Grand Tour

In Europe, from the early modern period, travel and tourism were seen as part of expanding and acquiring knowledge. From the late fifteenth century, the sons of the upper classes were sent to tour abroad as a means of completing their education. As tutors took their young male charges to cultural sites, the process evolved as an induction into gentlemanly society. The Grand Tour, as this practice would become known in the late seventeenth century, caught on. Over the course of the seventeenth and eighteenth centuries, thousands of Britons, Germans, French, and Russians traveled around the continent, principally to France, Italy, Switzerland, and Germany. Wealthy Britons especially, inspired by the aesthetic principles of the picturesque and Edmund Burke's *Philosophical Enquiry into the Origin of our Ideas of the Sublime and Beautiful* (1757), moved between the mountainous

This itinerary traces a pilgrimage from London to Jerusalem made by the thirteenth-century historian Matthew Paris, a monk at the Benedictine Abbey of St. Albans.

regions and the major places of cultural importance as ascribed by the many guidebooks published in the period. (The English term “tourist” was first coined in the late eighteenth century to describe them.) Tourists often brought back souvenirs during this period, and collections of geological, archaeological, and other items picked up on tour were common in homes of the wealthy all across Europe. (The term *wunderkammer* (“cabinet of curiosities”) was used to describe such collections.) The Grand Tour elicited a deliberate “seeking out” of culture in an effort to broaden the mind.

The eighteenth and nineteenth centuries saw travel more through the lens of scientific exploration and expedition. The Age of Enlightenment transformed the approach to natural history, and scientists—particularly naturalists and botanists, both professional and amateur—traveled across the world in search of new information and a reordering of existing classifications through new biological systems. People from Britain, France, Germany, and America traveled to Asia and Africa exploring and collecting. Empire played a major role in this practice as Europeans traveled to their nation’s colonies discovering new species of plants and animals, reported on the cultures of indigenous populations, and mapped the territories. Despite the curiosity for discovering new cultures throughout the eighteenth and nineteenth

century, travel was used as a means of dominating the landscape and native people, particularly in colonial Africa, Asia, and South America. Travel was still very much a privilege of the upper classes, but this changed during the nineteenth century.

Trains and Steamships

The Industrial Revolution’s impact on technology and work patterns transformed tourism in Britain and northern Europe. In particular, the revolution in transportation technology and the emergence of a tourism industry opened up leisure travel to greater numbers of people and made the process of traveling much more organized.

The railway, in Britain and later in Europe and North America, allowed greater access to a destination at greater speed. Thomas Cook’s organized trip from Leicester to Loughborough in 1841 saw the start of mass rail travel for pleasure trips. During newly allocated holiday time, factory workers from the industrial heartlands of England were able to travel on the specially built railway lines to seaside resorts. These trends were also evident in North America. As the population spread west over the course of the nineteenth century, roads and then railways were constructed to facilitate travel across the country. Sailing ships were replaced by steamships and allowed greater

When you travel, remember that a foreign country is not designed to make you comfortable. It is designed to make its own people comfortable. • Clifton Fadiman (1904–1999)

Emil Brack (1860-1905), *Planning the Grand Tour* (n.d.). Oil on canvas. The Grand Tour elicited a deliberate “seeking out” of culture in an effort to broaden the mind.

access to the world, not only for trade and scientific exploration but also for leisure. Other developments, such as the opening of the Suez Canal in 1869 also facilitated this movement abroad. From the late nineteenth century, travel to America and Australasia was a popular undertaking by the more wealthy members of the European population. In a continuation of the Grand Tour, people moved around the major cities and sites of interest. The technology of the Industrial Revolution, accompanied by the emergence of a tourism industry, opened up the world. The emergence of tour operators and travel agents in Britain and America, particularly Thomas Cook (in the United Kingdom), and the international financial services of American Express (which began issuing the Travelers Cheque in 1891), brought further organization

to tourism. In Britain, Thomas Cook provided organized trips to spa towns and seaside resorts and then, in 1855, to Europe and further afield, eventually providing tours to Australia and New Zealand beginning in the 1880s. These developments over the nineteenth century made tourism accessible to broad swathes of society and paved the way for the growth of the tourism industry in the twentieth century.

Automobiles and Airplanes

The relative peace in Europe in the late nineteenth century meant that these trends in tourism continued, and a growth in travel occurred up until World War I. In the years after the war, the motor car emerged as the new technology to dominate tourism. The popularity of the car for leisure travel began in the United States and moved to Europe over the course of the 1920s and 1930s. Once again linked to the fashions of the Grand Tour, motoring holidays saw tourists seeking out picturesque sites and points of interest. The car was much more dominant in the United States than in Europe; the first half of the twentieth century saw the car emerge as the main form of transport and the construction of highways and motels facilitated this desire for travel. The majority of car travel was domestic, challenging the dominance of the train, while the emergence of passenger air travel in the mid-twentieth century saw a dramatic shift away from surface transport for longer trips.

Just as roads, steam power, and cars had previously, airplanes transformed the way people traveled and opened up new regions, cultures, and populations to tourism. Initially used for commercial purposes, airplanes began taking passengers in the 1920s. Air travel for tourism took off after World War II with the development of the jet engine, which increased the speed and range of aircraft, making international travel more accessible. With greater affluence on both sides of the Atlantic from the 1950s onward, the tourism industry responded to demand for overseas travel by introducing cheap package holidays. This heralded the industrialization of the industry and the onset of mass tourism in the second half of the century.

This 1902 poster advertises tours organized by Thos Cook & Son, the “role model” for many travel agencies in the twentieth century. Thomas Cook Archive.

The Twenty-First Century

The twenty-first century has seen fundamental shifts in tourism, caused primarily by the role of the Internet and the use of tourism as a target for terrorism. The terrorist attacks of September 11, 2001, had a big impact on international tourism, heralding a new regime of travel security. Globalization means that while historic trends in tourism will continue, new players are emerging, particularly China, which is set to become the largest generator of international

tourism in the world. These trends are set against a background of (i) short-term reductions in demand for tourism caused by the global economic recession of 2008 onwards, (ii) ongoing concerns that the consequences for tourism on the environment are unacceptable, as for example the impact on the flora and fauna of sensitive areas, and (iii) a longer term concern over climate change and whether, in fact with its significant contribution to carbon emissions, tourism should continue at all. Of course, the tourism sector in the twenty first century is attempting to mitigate these impacts through alternative formats such as eco-tourism and sustainable tourism and these trends are set to intensify in the future.

Despite vast differences from the industry it is today, tourism as a process can be traced back to ancient times. Changes in technology, trends, and fashions have facilitated a transformation in the way people travel over the centuries. From the early periods of ancient history, travel, whether through trade, pilgrimage, a search for knowledge or for pleasure, has seen the exchange of ideas, populations, and trends.

Trade Cycles

Trade cycles are fluctuations in patterns of prosperity and depression that have occurred throughout history as the result of shocks such as wars, oil crises, new technologies—or as the result of waves of investor optimism and pessimism. Economic growth has not been, and is unlikely to be in the future, smooth and steady, but will consist of fluctuations around a trend.

Since the time of the Old Testament, when Joseph prophesied to Pharaoh that Egypt would experience seven fat years followed by seven lean years, economic activity has been characterized by wavelike rhythms and by longer-term trends and irregular fluctuations. Boom periods of prosperity and expansion are succeeded by recessions and depressions, which in turn give way to recovery and renewed prosperity. In preindustrial societies, cycles and fluctuations in the weather, which affected harvests, had the largest effect on the level of prosperity, while all aspects of life were affected by the cycle of the seasons. The “little Ice Age” of the fourteenth century was a period of economic depression in Europe. In the 1870s the economist and philosopher William Stanley Jevons argued that an eleven-year cycle in sunspots caused cycles of the same average length in the weather, harvests, and economic activity, but this theory has since been rejected so completely such that in current macroeconomics the term *sunspots* is used to refer to any intrinsically irrelevant variable.

Beyond the weather and the seasons, preindustrial cycles and fluctuations in economic activity were set off by real shocks (wars, inventions, and plagues such as the Black Death of 1348–1351, or discovery of

trade routes such as the sea route around the Cape of Good Hope to Asian spices) or by monetary shocks (such as the “price revolution of the sixteenth century,” as silver from the new Spanish colonies in Mexico and Upper Peru raised Europe’s money supply and quadrupled its prices). The Black Death, which raised the amount of arable land per person by killing a third of Europe’s population, was followed by more than half a century of high real wages. A financial shock, such as the failure of the Bardi and Peruzzi banking houses in Florence when Edward III of England defaulted, rippled through the commercial cities of northern Italy and Flanders and their trading partners around the Mediterranean and Baltic. Lord Overstone, a banker, introduced the phrase *cycles of trade* in the 1840s, and in 1862 the economist Clément Juglar published his pioneering history of commercial crises and their periodic recurrence in England, France, and the United States (including cycles in French marriage, birth, and death rates). The phenomenon itself was much older: the economist Thomas Ashton identified twenty-two economic fluctuations in eighteenth-century England, finding their origins in Britain’s wars, seventeen financial crises, and eleven bad harvests.

Long Waves

In 1925 the economist Nikolai D. Kondratieff observed recurring long waves of fifty to sixty years (twenty to thirty years of rapid economic growth, followed by an equally long period of slow growth) in British, French, and U.S. data on output, prices, wages, and interest rates from the Industrial Revolution onwards. This analysis led to his arrest and death in Stalin’s purges

More than two-fifths of German industrial workers were unemployed by 1932. Poster of a distraught mother and her hungry children reads, "Farmers, do your duty! The cities are starving." Library of Congress.

and the suppression of the Moscow Business Conditions Institute because of the implication that the Great Depression following the Wall Street crash of 1929 was not the final crisis of capitalism, but merely a severe downturn that would be succeeded by an upswing in the capitalist economies.

The political economist Joseph Schumpeter attributed the economic expansion at the start of each Kondratieff wave to a clustering of technological innovations that both improved productivity and induced a surge of investment: water power, cotton textiles (spinning jenny, power loom, cotton gin),

and iron (coked coal replacing wood as fuel) in the first Kondratieff wave from the 1780s (the Industrial Revolution); steam, railways, and steel in the second Kondratieff wave in the middle of the nineteenth century; chemicals, electricity, and automobiles in the third wave that began in the 1890s. Later writers emphasize electronics, petrochemicals, and aviation in the fourth wave and computers and the Internet in a fifth Kondratieff wave. Such breakthroughs in technology and organization are instances of "creative destruction" rendering obsolete the physical and human capital of the previous techniques of production.

**"Black Monday," 28
October 1929, Wall Street.**
The stock market fell 12.8
percent and dropped almost
as sharply the following day.

Schumpeter interpreted economic fluctuations as the aggregation and interaction of three superimposed cycles: a short Kitchin cycle (inventory cycle) averaging forty months duration, a Juglar cycle of nine or ten years, and a Kondratieff cycle of forty-eight to sixty years, generated by clusters of innovations of different importance and gestation. By contrast, the economist Solomos Solomou concludes that the evidence is against the existence of a Kondratieff long wave in output or prices, that the leading industrial economies have not shared the same phases of boom and bust over long cycles, and that innovations have not been clustered in the way suggested by Schumpeter. But Solomou found more evidence to support the existence of a Kuznets cycle averaging twenty years in length (varying from fourteen to twenty-two years), while other authors had argued that the apparent Kuznets cycle was an artifact of the filtering techniques used to decompose time series into trend, cycles, and irregular fluctuations. Increasingly, economists and economic historians have become skeptical of the existence of true economics cycles—persistent rhythms whose average length and size remains unchanged—but recognize that responses to real and monetary shocks can be oscillatory, moving through successive phases of expansion and contraction but with the response to each shock gradually fading away.

Depressions

The depression of 1873 to 1896 was a long period of generally declining commodity prices and rising purchasing power of money, as the demand for real money balances grew faster than the world's supply of gold. Such falling price levels were perceived at the time as depressing industry and commerce, but the period 1873–1896 is viewed in retrospect as one of depression in prices and nominal interest rates rather than in real output. The deflation was reversed by gold discoveries in South Africa and the Klondike and by the invention of the cyanide process for extracting gold from low-grade ores. The Great Depression of the 1930s, following the Wall Street crash of October 1929 that ended the U.S. stock market bubble of the late 1920s, was a depression in real output and employment as well as in prices. A quarter of the U.S. labor force and more than two-fifths of German industrial workers were unemployed by 1932, more than one-fifth of British workers by 1931. Bank failures and the fear of additional possible bank failures, with no deposit insurance, caused depositors to withdraw cash from U.S. banks, and banks to hold more reserves against their deposits, causing the U.S. money supply and price level to fall by a third or more. The gold standard, requiring the convertibility of national currencies into gold and other currencies at fixed rates, was seen as spreading the depression from one

Commerce is the cure for the most destructive prejudices. • Charles de Montesquieu (1689–1755)

country to another, as national central banks were obliged to contract their money supplies to defend the exchange rates in the face of gold outflows. A country could maintain a fixed exchange rate only if the prices of its goods fell by the same proportion as the price level declined in its major trading partners and competitors. These pressures led to the breakdown of the gold standard, with Britain leaving in September 1931 and the United States in 1933. Another consequence was declining international trade and movement away from global economic integration, as countries responded to high unemployment and declining production by imposing tariffs and quotas on imports and subsidizing exports. Such moves increased friction between nations, and together with high unemployment, especially in Germany, helped to undermine democracy and international peace in the years leading to World War II. Similarly, the “golden age” of largely sustained western European, North American, and Japanese prosperity from 1950 (after the Marshall Plan and comparable American aid to Japan assisted postwar reconstruction) until the first oil shock of 1973 contributed to the growth of democratic institutions and international stability.

Trade Cycles in the Present and the Future

Do business cycles still exist? Are periods of economic boom still followed by slumps? The Great Depression of the 1930s and the associated rise of Keynesian macroeconomics (following the economic and monetary theories of British economist John Maynard Keynes) led national governments in the leading industrialized countries to accept responsibility for stabilizing the economy; they used monetary and fiscal policies to manage aggregate demand to try to smooth out fluctuations in output and employment. The larger share of government spending in the economy also acted as an automatic stabilizer, since government spending would be maintained when private consumption and investment fell in a recession, while such structural reforms as deposit insurance made the financial system less vulnerable to runs on

banks by anxious depositors. Swift reaction by the U.S. Federal Reserve System prevented the abrupt stock market slump of October 1987 from having the wider consequences of the stock market crash of October 1929. Even with the OPEC oil price shocks of 1973 and 1979–1980, the world economy has clearly been more stable since World War II than it was between the two world wars. However, the economist Christina Romer has argued, controversially but influentially, that the apparent greater stability of the U.S. economy after World War II than before World War I is nothing more than a statistical artifact, resulting from the ways in which retrospective national accounts data were created for the pre-1914 United States. The global financial crisis of 2007–2010, referred to by many as the worst financial crisis since the Great Depression, and triggered to a large extent by the bursting of the U.S. housing bubble, is offered by some as evidence of this.

Prior to the global financial crisis, from the 1980s, governments were less influenced by Keynesian arguments for government stabilization of output and employment to smooth out the business cycle. Instead, the emphasis was on limiting inflation and on public policies to promote long-run growth of productive capacity. Booms and recessions continue to succeed each other, transmitted internationally through trade and investment flows in an increasingly integrated global economy, but with different countries not always in the same phase of the cycle at the same time. Since the breakdown in 1973 of the Bretton Woods system of fixed exchange rates, these fluctuations in prosperity and international payments have been accompanied by fluctuations in exchange rates (with the adoption of the Euro, initially by eleven European countries in 1999, reducing the number of exchange rates and currencies, and thus reducing the possibilities for variation). Economists now use the terms *trade cycles* or *business cycles* to mean economic fluctuations, without any implication that the fluctuations are cycles of fixed duration.

The fluctuating pattern of economic prosperity and depression has had deep social effects throughout history, and fluctuations continue to recur, as the result

of shocks such as the creation of the OPEC oil cartel, the invention of a new technology, wars, or weather, or as the result of waves of optimism and pessimism among investors. The process of economic growth has not been, and likely will not be in the future, smooth and steady, but will consist of fluctuations around a trend.

Trading Companies, Iberian

The first great European merchant empires to establish global commercial networks during the early modern era were those of Spain and Portugal, on the Iberian Peninsula, during the fifteenth and sixteenth centuries. But their trading companies appeared later than, and in response to, those of their European rivals, especially the Dutch and the English.

Those commercial trading networks of Spain and Portugal on the Iberian Peninsula provided substantial revenue for both countries and galvanized rival European powers to tap into lucrative markets in the Americas, Asia, and Africa, where, for instance, they traded in European horses, leather, textiles, pepper, Sudanese ivory, metal products for luxury goods such as gold, and slaves. Because the Iberian powers had the advantage in first establishing these economic structures with few other European rivals in these global markets, Iberian companies were not necessary, at least initially. Spanish and Portuguese trading companies patterned along lines similar to the companies of their Dutch and English rivals appeared during the seventeenth and eighteenth centuries.

Exploration and Trade Expansion

The chance to profit from commercial opportunities drove both the Portuguese and the Spanish in their exploratory voyages, which were outgrowths of those conducted during the Middle Ages. Two such voyages were the rediscovery of the Canary Islands in the mid-1300s by Genoese sailors in service to Portugal and the 1291 voyage of Ugolino and Vadino di Vivaldi,

who disappeared near Safi, Morocco, due to their attempt to circumnavigate Africa.

Beginning in the early fifteenth century, the Portuguese extended their influence in the Atlantic Ocean through a series of journeys down the West African coast. In exchange for Iberian agricultural products, the Portuguese received gold, fish, and slaves from North Africa. Establishing colonies and sugar plantations in places such as the Azores and Madeira islands permitted the Portuguese to obtain a geographic advantage in their further exploration of economic opportunities in Africa.

The foundation of fortified trading posts was significant for the development of Portugal's economic empire. São Jorge de Mina, located in modern Ghana, was one such post, where the Portuguese traded European horses, leather, textiles, pepper, Sudanese ivory, metal products for luxury goods such as gold, and slaves. Profits received from this trade helped the Portuguese to fund further explorations down the coast. These posts, established soon after the first Portuguese incursions were made into new areas, were designed to control trading routes. Through the supposed military superiority of their ships and cannons, the Portuguese sought to force other merchant vessels to dock at these posts and pay duties. By the middle of the sixteenth century the Portuguese had more than fifty such fortified entrepôts, extending from West Africa to East Asia. But thanks to the strength of Muslim, Indian, and Malay merchants, combined with the dearth of Portuguese vessels, Portuguese dominance of the Indian Ocean shipping lanes was never a foregone conclusion.

Spain, though it maintained a distinct economic presence in the Far East, focused its mercantile

attentions largely toward the Americas. Spain founded an empire based on land rather than setting up a string of trading ports as did the Portuguese. The 1545 discovery of enormous deposits of silver in Potosí, located in modern Bolivia, was a watershed event for Spain's imperial history. Mining became a singularly important industry within Spanish American territories, and the silver galleons that sailed the seas from Acapulco to Manila were crucial to Spain's political and mercantile empire. Demand for silver, the principal currency of the Chinese economy, was very high within Asian markets. Between 1570 and 1780 CE anywhere from 4,000 to 5,000 tons of silver crossed the Pacific Ocean. Because the Spanish crown received a fifth of the bullion, the trade in gold and silver across both oceans was quite lucrative.

Trading Companies

Though Portuguese and Spanish trading companies are not as well known as their English or Dutch counterparts, such as the English East India Company or the Dutch United East India Company (Vereenigde Oost-Indische Compagnie), privileged Iberian trading companies nonetheless played a substantial role in the early modern era. In 1685, the Portuguese founded a company for the purchase of slaves, one of the more profitable aspects of their transatlantic trade. It was not until the eighteenth century that the Spanish formally chartered several companies for their trade in the Indies. The 1728 founding of the Royal Guipuzocan Company of Caracas linked Venezuela with the Basque country in Spain and monopolized the cacao market until 1780. Additional Spanish companies included the Royal Company of Havana, founded in 1749 and designed to spur interest in Cuban agriculture and trade; the 1747 Royal Company of San Fernando of Seville, which focused on parts of the South American trade that were not covered by other companies; and the Royal Company of Barcelona, founded in 1765, which covered trade with the islands of Santo Domingo, Puerto Rico, and Margarita. These companies, designed to

revive Spanish fleets and drive out foreign merchants, did not monopolize trade in the Caribbean for long. The Seven Years' War (1756–1763) saw the Spanish government open trade to Spanish ports left out of official companies' trading partnerships. In 1778, the government allowed partial foreign shipping into the Indies and restrictions on free trade were lifted completely in 1789.

Trading Patterns, Ancient American

Trade was widely practiced in all parts of the ancient New World, among societies of all levels of social complexity, from the earliest hunter-gatherers to late prehistoric empires like the Aztec and Inca. But the high costs associated with overland human transport produced a volume of long-distance trade lower than that found in many other ancient societies.

The native peoples of the New World exhibited a great diversity of trading patterns before the European invasion. In most ancient American societies, trade and exchange were strongly embedded within social institutions and practices. The long-distance trade identified by archaeologists was typically only one component of wider processes of social interaction that included exchanges of ideas and information, warfare and diplomacy, marriage alliances, and migrations of peoples. Trade assumed an independent commercial status only among the late states of Mesoamerica (Mexico and northern Central America).

Earliest Inhabitants

The timing of the initial migrations to the New World is a topic of considerable debate. Regardless of their actual age, however, the earliest archaeological sites in North and South America provide evidence for a low level of long-distance trade. During this time, known as the Paleoindian period (c. 15,000 BCE–8000 BCE), small bands of hunters and gatherers traded projectile points and other tools made of high-quality chert (a variety of silica) and other varieties of stone over

moderate distances. The finely made and distinctive Clovis spear points were used over much of North America. These objects were made separately in many regions, and their similarities derive from a common technology that points to long-distance interaction throughout North America. Obsidian, a volcanic glass from which extremely sharp cutting tools were made, was first traded in the Paleoindian period. Obsidian occurs geologically in only a limited number of mountainous areas in western North America, Mesoamerica, and the Andes. Each source area has a distinctive chemical “fingerprint” in the occurrence and quantity of trace elements. When subjected to any of a number of analytical techniques for measuring trace elements, an obsidian artifact’s geological place of origin can be traced.

In most parts of the New World, the Paleoindian period was followed by the Archaic period (starting c. 8000 BCE and ending at different times in different areas). This was a time of growing populations, increased reliance upon plant foods, and growing technological sophistication. In Mesoamerica, the Andes, and the Amazon, plants and animals were domesticated at this time. The Archaic period furnishes evidence of increasing long-distance trade of stone tools. Although the evidence for trade is clear in the Paleoindian and Archaic periods, the overall volume of exchange was low and people obtained most goods in their local area. Trade was probably organized in what archaeologists call “down-the-line trade,” in which trade goods move through reciprocal exchange from group to group without merchants or long-distance exchange expeditions.

Nay, be a Columbus to whole new continents and worlds within you, opening new channels, not of trade, but of thought. • **Henry David Thoreau (1817–1862)**

This Cayuse woman from Oregon wears shell disk earrings, a shell bead choker, and shell beads, items used since ancient times for trade and as burial goods. Photo by Edward Curtis circa 1910. Library of Congress.

North America

The roster of North American long-distance trade goods increased dramatically with the end of the Archaic period to include marine shell, ceramics, and objects made of copper, galena, obsidian, and other types of exotic stone. The frequencies of imported goods were typically much higher than in Paleoindian and Archaic times. Obsidian found at sites in eastern North America and marine shell ornaments at sites far inland show trade over long distances. Several later cultures are noteworthy for high quantities of imported goods. The Hopewell culture of the North American Midwest, for example, is best known for its elaborate public ceremonialism centered on earthen

mounds and open plazas. Some Hopewell burials and other offerings contained thousands of ornaments and other finely crafted objects, many of which were imported from great distances. Imported burial goods include at least ten types of native copper ornaments, finely-made stone bifacial tools, obsidian objects, mica mirrors, smoking pipes of clay and stone, ornaments of human bone and bear's teeth, tools of deer bone, quartz crystal, shell beads, and silver objects.

The emphasis on ornaments among the imported goods of the Hopewell and other North American cultures suggests that social factors were more important than strictly economic factors as stimuli for trade. Elaborate ornaments and exotic goods were most likely used in ceremonies and at other public gatherings (before being deposited in offerings) to communicate information about social identity and status. They probably served as sources of prestige for high-ranking individuals. This pattern continued in the most politically complex and spatially expansive North American culture, the Mississippian culture of southeastern and midwestern North America (c. 1000–1550).

Archaeological sites of the Mississippian culture are larger and more numerous than those of earlier cultures. The largest Mississippian site—Cahokia—was a true urban center with a substantial population, monumental architecture, powerful rulers, and various types of craft specialists. Many archaeologists classify Cahokia as an example of the chiefdom form of political organization. Cahokia was located in the American Bottoms (in Illinois, across from St. Louis), the largest expanse of rich alluvial floodplain along the Mississippi River. This region had numerous Mississippian settlements, all engaged in agricultural production and many with active craft industries. Exchange was extensive on both the regional level (linking the sites in the American Bottoms area) and the macroregional level, as evidenced by a variety of exotic imported goods found in excavations. Although some utilitarian goods were widely traded—particularly agricultural hoes produced from high-quality chert—most Mississippian trade goods were ornaments, ritual items, and the raw materials used to

Mayan burial site. Archaeologists have found evidence of imported luxury items by examining burial offerings and other excavations. Photo by Arturo Delfin.

produce such goods (including copper, marine shell, and a variety of precious stones). The organization of Mississippian trade probably included down-the-line trade, gifts among localized elites, and exactions of taxes or tribute from subject populations.

Mesoamerica

Mesoamerica is a cultural area whose numerous peoples and cultures shared a variety of traits and

practices. The commonalities that defined Mesoamerica were sustained by systems of long-distance interaction that included exchanges of both goods and ideas. Although long-distance trade goes back to the earliest inhabitants of Mexico and Guatemala, the distinctive exchange systems that created and defined Mesoamerica as a distinctive area developed after the start of the Formative period (c. 1600 BCE). In cultural terms, the Formative period saw the spread of a way of life based upon agriculture, sedentism (year-round villages), and

pottery. Chiefdoms soon developed in several parts of Mesoamerica, including the Pacific coast, the Valley of Oaxaca, central Mexico, and along the Gulf of Mexico (home of the Olmec culture). The rulers of these polities exchanged a number of goods, including jadeite, serpentine, and other precious stones; obsidian tools; ceramic vessels; iron ore mirrors; shell ornaments; and various animal products used in ritual, such as sting-ray spines and turtle shells. As in the case of Hopewell and Mississippian exchange in North America, most trade goods were luxury goods used in social display and ceremonial performance, and the production, exchange, and consumption of these goods was probably under the control of chiefs and elites.

The Classic period in Mesoamerica (c. 250–900) was marked by the rise of powerful states in most regions. In the jungle lowlands of Guatemala and Mexico, Mayan kings ruled city-states from urban centers with abundant monumental architecture. Imported luxury goods were essential elements in the elaborate public performances and lavish lifestyle of these rulers. Kings often adorned themselves with imported precious stones (such as jadeite and obsidian) and headdresses of tropical bird feathers. They sponsored exclusive elite feasts at which foodstuffs such as cacao and other delicacies were served from elaborate painted pottery vessels. Obsidian had to be imported from distant sources, and most Classic-period Maya obsidian objects functioned in the realm of social display and rituals.

The contemporary Teotihuacán state of central Mexico presents a cultural and economic contrast to the Maya polities. Less flamboyant than their Maya counterparts, the rulers of Teotihuacán concentrated more effort on trade and craft production. Located near several major geological sources of obsidian, Teotihuacán controlled the production and trade of obsidian tools and jewelry in northern Mesoamerica. Excavations have located numerous craft workshops, and Teotihuacán houses have yielded goods imported from all parts of Mesoamerica. Teotihuacán exports—found all over Mesoamerica—include ceramic vessels in addition to obsidian objects. Some kind of special economic and diplomatic relationship existed between Teotihuacán and the city of Monte

Albán in Oaxaca, and a colony of merchants from the latter area has been excavated at Teotihuacán.

The transition to the Postclassic period (900–1520) was marked by a significant increase in economic activity in most parts of Mesoamerica. For this period, written historical records supplement archaeological evidence, and it is clear that highly commercialized long-distance trade flourished.

Caribbean Islands

The initial inhabitants of the Caribbean islands, most likely immigrants from the Mexican mainland, traded with peoples of northeast South America for crystals and other ritual items. A major migration from South America began c. 2000 BCE, bringing new peoples into the Lesser Antilles and eventually to most of the Caribbean. These “Saladoid” peoples, ancestors of the Tainos, maintained contact with people in South America through trade in a variety of goods. From earliest times, the peoples of the Caribbean were expert mariners who used dugout canoes to undertake both local and long-distance voyages. Trade within islands and between adjacent islands was extensive in all periods, whereas the extent of long-distance trade varied across time and space.

The major long-distance trade goods found at archaeological sites in the Caribbean are chert (for flaked stone tools), pottery and volcanic pottery temper, beads made from a variety of exotic stones (e.g., quartz crystals, amethyst, and diorite), and ornamental carved stone objects (including distinctive stone pestles). The trade connections with South America were still going strong with Columbus arrived in the Caribbean. He noted ornaments of a gold-copper alloy worn by Taino chiefs. The Taino worked locally-occurring gold but did not cast metal, and these ornaments must have been obtained through trade with the South American mainland.

South America

As in North America and Mesoamerica, long-distance exchange in South America started with the

earliest hunter-gatherers of the Paleoindian period. Exchange throughout the Amazon Basin was probably extensive in most periods, but since the bulk of the material culture consisted of perishable goods this trade is difficult to document archaeologically. Early explorers and travelers reported active riverine exchange systems that some scholars treat as models for earlier periods. For a variety of reasons, trade is easier to study archaeologically in the Andean region. After the development of chiefdoms and states in the Andes, several goods of limited occurrence were widely traded over great distances. Of these goods, obsidian and marine shell stand out. There are fewer geological sources of obsidian in the Andes than in Mesoamerica, but Andean peoples made active use of the superior cutting edges of this stone in all periods. Marine shell was another important trade good in the Andes. Particularly valued was the colorful shell of the spiny oyster (genus *Spondylus*), used to make ornaments and ritual goods. These shells occur naturally only along the Pacific coast of Ecuador and Central America, and their presence at sites in the Andes was due to long-distance exchanges with northern groups. Metallurgy developed early in the Andes (c.1800 BCE), and objects of gold, silver, and bronze were widely traded.

The entire Andean zone was linked into a single cultural and economic system during three periods, called “horizons” by archaeologists. The Early Horizon (800–200 BCE) was dominated by the Chavín culture. The central settlement, Chavín de Huántar (in present-day western central Peru), has yielded archaeological evidence of exchange with both the Amazonian lowlands and the Pacific coast. Mechanisms of long-distance interaction included both the exchange of goods and the spread of the Chavín art style, which was probably the material expression of a common religious system that linked numerous localized small polities. The Middle Horizon (600–1000) witnessed the spread of two major art styles centered on the cities of Huari and Tihuanaco (in the central and southern Andes, respectively). Huari was the capital of a territorial empire in which both trade and the imperial art style contributed to political integration and domination. During the Late Horizon (1400–1530), the Inca

Empire expanded rapidly to control nearly the entire area of the Andes and the Pacific coast.

The peoples of the Andes made use of a number of distinctive trading patterns quite different from those of Mesoamerica and North America. Most important was a strong desire for self-sufficiency on the part of villages and polities. The varied environments of the Andes, caused primarily by differences in elevation, are often in close juxtaposition. Rather than having villages in each zone specialize in local products and trade with one another (as happened in Mesoamerica), villages and polities sent out temporary settlements to exploit different zones so that each social unit could be self-sufficient by controlling the products and resources of many zones. This pattern was first described by the anthropologist and historian John Murra, who called it “verticality.” The Inca rulers adapted self-sufficiency and verticality to their empire, with the result being a bureaucratic, state-run economy. Taxes were paid in labor as well as in goods. Managers organized labor parties and tracked the storage and movement of raw materials, flocks of llamas and alpacas, foods, and craft products. Money, markets, and independent merchants did not exist in the Inca Empire, although these institutions did occur among some Andean groups outside the reach of the empire.

Ancient American Trading Patterns

Native inhabitants of North America, the Caribbean, and early Mesoamerica traded mostly ceremonial and luxury goods, at low quantities in the first two areas and at higher quantities in Mesoamerica. Late Mesoamerican peoples adopted commercial exchange institutions that raised the volume of trade and extended the diversity of goods exchanged. In the Andes, a drive for self-sufficiency led to distinctive state-run trade systems. Overall, the high costs associated with overland human transport produced a volume of long-distance trade lower than that found in many other ancient societies.

Trading Patterns, Ancient European

Geographical advantages on the peninsula that is Europe enabled the development of trading networks from an early date. Rivers and long coastline provided the highways by which goods and peoples moved with increasing freedom. Amber, metals, and grain were early commodities; urbanization brought roads, empires, and commercial networks that reached their peak in the second century CE.

Europe is a broad peninsula spreading westward from the Ural Mountains. Black and Mediterranean seas wash its southern shores, the Arctic Ocean its northern shores. To the west, Europe is bounded by the Atlantic Ocean, in which the great continental islands of Britain, Ireland, and Iceland sit. The coastal extremities of the greater European peninsula are in turn fragmented into number of smaller peninsulas: the Italian, the Greek, the Iberian, and the Scandinavian. The land mass is mountainous, although not impassably so, and the plains are intersected by great rivers that flow from the mountain ranges to the sea. Great river systems, in particular the Rhine, the Danube, the Dnieper, and the Rhone, connect the coast with lands far inland. These geographical advantages enabled the development of trading networks from an early date. In the absence of roads, the rivers and long coastline provided the highways by which at first goods and later people moved with increasing freedom.

The Foraging Era

Europe was peopled by anatomically modern humans (Cro-Magnons) from about forty-five thousand years

ago. Habitation was initially limited to the more temperate southern coastal lands, because further north much of the landscape was dominated by the glaciation of the last great Ice Age. Such severe climatic conditions demanded ingenuity on the part of those humans who moved into those regions. Over millennia, a portable and flexible technology was developed in which there was a high demand for fine-grained stone cores (shaped but not completed stone tools). While it is clear that human bands dispersed during the long winters, all the better to subsist, there is good evidence to suggest that they gathered during the summers. For example, there is no doubt that they exchanged objects and, as a result, some artifacts moved a very long way from their initial point of origin. Baltic amber has been found at Cro-Magnon sites in southern Europe and seashells and sharks' teeth far inland.

The Neolithic Era

The melting of the ice sheets, with the resulting rise in sea levels, was complete by about 10,000 BCE. It was only then that Europe, as we know it, finally took shape. The North Sea and the Black Sea were flooded; rising sea levels also created the Aegean archipelago, cut Sicily off from Italy, and divided Sardinia from Corsica. The principal cultural development of the Neolithic is farming on dry, nonirrigated land. This resulted in the emergence of village communities and the development of more specialized technologies. It is also possible to begin to identify the emergence of an agricultural surplus as a tradable commodity. Luxury items have been found very far inland: in particular, shell jewelry of Aegean origin at sites

Celtic art object made of iron. From *Scotland in Pagan Times: The Iron Age*, by Joseph Anderson (1832–1916). New York Public Library.

in Germany and Hungary. Obsidian from the Lipari islands has been found in Malta, and the island of Melos served as a source for much of the obsidian used in the eastern Mediterranean. It has been argued that the trading networks established in the Neolithic of Mesopotamia/Anatolia for the distribution of obsidian established the trading patterns that dominated the ancient Mediterranean world.

It is unlikely that such goods were taken directly from the place of manufacture to the sites where they have been found. In all likelihood, they were transported indirectly through a series of relays. This kind of “relay trade” is the principal way in which goods were moved long distances for most of antiquity, and it remains significant that only luxury goods were capable of being moved in this way, since only they could sustain the margins being added at each point of exchange.

The Amber Route

A good example of this early relay trade is amber, a commodity that was highly prized from the foraging era onwards, and the principal source of which, in Europe, was the Baltic region in the vicinity of the modern Russian territory of Kaliningrad. Very sophisticated networks for the transportation and distribution of Baltic amber were established during the Neolithic and continued into the classical period.

Amber is found in the early Bronze Age graves of Mycenae, the middle Bronze Age ship wrecked near Ulu Burun, and the magnificent tomb of the Pharaoh Tutankhamen.

The amber was transported along the coast of the Baltic to the River Elbe. From there, it was taken far upstream. In southern Germany, it was transferred to transport overland, making the journey through the Alps and down to the Adriatic Sea. From ports on the Adriatic, it was transported, mostly through cabotage (that is, local trading networks), to the great economic centers of the ancient world.

The Metals Trade

The increased working in metal ores marked the end of stone-based technology. One stone that became extremely popular, where it was available, was raw copper. There were a number of major deposits of copper in European centers—in particular, the Balkans and the island of Cyprus. There were also smaller deposits elsewhere. When the frozen body of Ötzi, the Ice Man, was discovered in a glacier on the Austrian-Italian border, he was found to be carrying a copper axe, which had been quarried locally, and which he had (probably) worked himself.

Nevertheless, copper-producing regions became the centers of trading networks. In many cases, these simply followed the same patterns as those established in the Neolithic. Deep copper mines were already operating in the copper-rich region of eastern Serbia in the fifth millennium BCE. Copper from the Balkans supplied a rich culture across what is now Hungary, Rumania, and Yugoslavia. In the same way, copper from Cyprus supplied the needs of the eastern Mediterranean. It was in this region that it was discovered that copper could be alloyed with Anatolian tin to make bronze. This in turn drove a demand for the much scarcer ore.

The emergence of the demand for tin broadened the Mediterranean trading network. While there were sources of tin in the Mediterranean world, the major source was tin-rich Cornwall. Herodotus refers to Britain as “the Tin Islands” (*Cassiterides*) and

Roman legionnaires build a camp and excavate a road (at left); horses transport a ballista (bottom right). The sophisticated Roman road system accommodated the free and easy movement of goods. New York Public Library.

Cornish tin found its way to the Mediterranean, either by a short sea trip to the mouth of the Loire, then up the Loire and down the Rhone to the coast, or by a long sea trip through Gibraltar to southern Spain. Like the amber route, this tin route connected the extremities of the European world through a network of exchanges.

Other highly prized metals were also being increasingly traded over long distances. Spanish silver and Irish gold both found their way into the Mediterranean trading world. By the middle Bronze Age large amounts of metal were being extracted, smelted, and traded. The Ulu Burun wreck, for example, carried six tons of copper, all cast into distinctive “ox-hide” type ingots, slabs of pure copper cast into the shape of an outstretched ox-hide. It is significant that this form of ingot had become standard throughout the Mediterranean world by the second millennium BCE.

The Rise of Urbanism

One other highly significant feature of the second millennium BCE was the development of palace cultures, cities, and city-states. These created economic differential, the possibilities of economic specialization, and particular centers of demand. The earliest urban cultures were situated away from the Mediterranean world, in the river valleys of Mesopotamia, the Nile, the Indus, and the Yangzi (Chang). By the middle Bronze Age, however, there was an elaborate palace culture on Crete, and complex urban entities were forming in Greece and Italy. Cities provided fixed markets for goods and secure environments for the

storage or conversion of surplus. Cities became the principal points of exchange in the relay trade and of economic distribution for their surrounding regions. Trade became so important to the cities of the Mediterranean coast that by the first millennium BCE they were sending out trading colonies.

The Phoenicians sought to exploit southern Spain, setting up a series of trading and mining colonies referred to in the Greek sources as “Tartessus,” and in the following centuries, the Greeks followed suit. One Greek colony of great significance was that of Massilia (modern Marseilles) at the mouth of the Rhone River, a site that enabled considerable control of the tin trade, challenging the Phoenician (increasingly Carthaginian) control of southern Spanish ports. Another was the city of Byzantium, located strategically on the Bosphorus, the narrow strait between the Black Sea and the Sea of Marmara, and therefore well situated to take advantage of trade between the cities of the eastern Mediterranean and the cultures surrounding the Black Sea.

The Grain Trade

One significant result of the development of urbanism was that the growth of some cities outstripped the productive capacities of their agricultural resources. While an initial answer to this was depopulation through colonization, ultimately a number of cities needed to import food. Grain imports soon became important, particularly for the agriculture-poor Greek city-states. A particularly important maritime route was established between Athens, the hungriest of

No nation was ever ruined by trade. • **Benjamin Franklin (1706–1790)**

the cities, and the Bosporan kingdom in the Crimea. The ancient ports of the Crimea sent out shiploads of grain, receiving, in turn, bullion, wine, olive oil, and elegant pottery. In the same way, other Greek states maintained links with the agriculturally wealthy Greek colonies of Sicily.

By the fifth century BCE, the entire Mediterranean was a well-travelled highway, serving the hungry markets of Greece, Anatolia, and Syria. There are two clear indicators of this: the introduction of coinage in Anatolia in the sixth century, which made processes of exchange easier, and the growth of piracy. While briefly suppressed by the Athenians in the eastern Mediterranean, it remained a major problem throughout the Mediterranean until the advent of Roman naval dominance in the first century BCE.

One feature of European trade that the pirates exploited was the trade in people as commodities: the slave trade. Large numbers of slaves came into the European economic system from the Eurasian steppe via the Black Sea. Others came from Thrace, Greece, and Anatolia, even well into the Roman period.

The Celts

Urbanism did not penetrate far north of the Mediterranean fringe. From the beginning of the first millennium BCE, the region between eastern Germany and the Atlantic coast of France was dominated by Celtic peoples. Principally farmers and pastoralists, they nevertheless exploited mineral deposits where they could find them. Salt mines in Austria were opened up and the salt exported to the Adriatic. Iron was also mined and worked in southeastern France and exported to the Etruscans and Greeks of Italy. Gold, wine, and elegant pottery wares were imported. In the same way, Celts also exported goods north, in particular bronze and iron artifacts. Technology was also exchanged. Celtic kingdoms began minting gold coinage, probably in imitation of Macedonian coinage, in the third century BCE. These exchanges were insufficient to prevent conflict between the Celtic and Mediterranean worlds, however. Major Celtic raids in the fourth and third centuries BCE saw a Celtic

kingdom established in Anatolia, and Rome itself sacked. It was, nevertheless, the Romans who brought regularity and security to western and southern European trade.

The Romans

When Julius Caesar conquered Gaul in the first century BCE, he brought it firmly into the Mediterranean economy. The subsequent conquests of Britain, Illyricum (the modern Balkan states), and the western part of Germany brought much of Europe into close economic contact. One major feature of Roman rule was the construction of roads; another was the suppression of banditry and piracy. Goods could travel long distances quite freely. Just as Athens had been dependent upon imported grain from the Crimea, the vastly bigger city of Rome received its grain in great freighters that sailed from grain ports in Africa, Sicily, and Egyptian Alexandria. The Roman network of roads and maritime routes made travel around and across the Mediterranean and deep into its European hinterland a relatively straightforward proposition.

Trading was no longer dependent upon cabotage, although that was still the most frequent type of trade. Rather, a number of mercantile diasporas were established throughout the Roman world and beyond it: Syrians, Jews, and Greeks established subcommunities within great cities like Rome and Alexandria. While this sometimes led to conflict, it also led to the spread of ideas. Christianity spread swiftly throughout the Mediterranean world and beyond it because of its strong base in Jewish Diaspora communities.

By the second century CE, the European economy was highly complex and interconnected. It has been spoken of as a segment in an increasingly complex world system. As such, it was subject to economic fluctuations. The long recession of the third century was felt throughout Europe, and it made Rome itself vulnerable to raids from predatory foreign peoples, which depressed the domestic economy even further. The subsequent recovery was partial, and by the late fifth century the Western Roman Empire had collapsed, disrupting ancient lines of trade and

communication. While the Eastern Roman (or Byzantine) Empire continued in existence for another millennium, it was never again so dominant a military and economic presence.

Trading Patterns, China Seas

The China Seas, a term coined by European navigators and cartographers, comprise five bodies of water adjacent to the country's 14,000-kilometer-long coastline. Although the Chinese were not generally seafarers, throughout much of China's history the major ports of the China Seas have been important in coastal, regional, and long-distance trading patterns.

For most of its long history, Chinese civilization has turned its back to the sea and has focused inward. The Chinese, as a general rule, have not been a seafaring people. Only a tiny fraction of the population of China derived their livelihood from maritime activities—fishing, overseas trade, piracy, or naval warfare. With the exception of the early fifteenth-century Admiral Zheng He, few Chinese mariners undertook long-distance voyages. But a coastline of about 14,000 kilometers (within today's borders of the People's Republic of China) makes maritime defense a significant factor of any government's security policies. Also significant is the establishment of port towns along the coast, many of them in the river estuaries of South and central China. The main economic function of these towns and cities was to organize exchange with commercial communities across the China Seas.

The Triple Function of the China Seas

China Seas is a summary term coined by European navigators and geographers and is rarely used in China. Chinese maps and geographic manuals distinguish between five different expanses of water adjacent to the Chinese coast: the Gulf of Zhili, called

Bohai in Chinese, south of Manchuria; the Yellow Sea, called Huanghai, between North China and the Korean peninsula; the East China Sea, called Donghai, into which the Yangzi (Chang) River discharges its waters; the Strait of Taiwan, called the Taiwan Haixia, separating that island from Fujian Province; and the South China Sea, called Nanhai, which is the maritime "foreland" of the southernmost Chinese province, Guangdong.

These maritime spaces are clearly separated from the high seas of the Pacific Ocean and the Indian Ocean. Yet, in an important way, they form a connection between both: for centuries after the arrival of European shipping in East Asia, the principal route from India into Pacific waters led through the Strait of Malacca and the South China Sea and then round the northern tip of the Philippine archipelago.

This fact points to the triple function of the China Seas, considered in terms of economic geography. In the first instance, they serve as an avenue for China's coastal trade. Coastal trade has always been vital for the integration not only of the various seaboard districts, but also of all the eastern provinces of China. Before the advent of the railroad it was indispensable for transporting bulky goods in a north-south direction. Second, the China Seas are the arena in which regional trade between China, Japan, and the countries of Southeast Asia unfolds. No other function is more important than this one. The China Seas gave rise to and still support a dense network of commerce connecting different economic systems which in many ways complement one another. Third, access to the oceans necessarily leads through the China Seas. In the long run, the China Seas' transit function is probably their least important aspect, assuming

This nineteenth-century map shows the ancient sea routes used from Greece and the Arabian Peninsula to and from China.

major importance only with the rise of the Guangzhou (Canton) trade in the early eighteenth century. But at least for modern times, it forms part of the complete picture. By definition, the predominant emporia are those that combine all three of these functional tasks. These major ports are simultaneously pivots of coastal, regional, and long-distance traffic and commerce.

Fourteenth-Century Trade in the South China Sea

The great achievements of Chinese nautical engineering have been reconstructed by modern scholars for epochs even earlier than the establishment of the empire in 221 BCE. Only with the Ming dynasty (1368–1644), however, does a comprehensive picture of maritime trade emerge. The basic type of ship, in use for many centuries, had already been developed during the tenth century. This “Fujian ship” (*fuchuan*), a safe, spacious, and fast vessel, proved admirably suited to the trading conditions in the China Seas.

It later evolved into the cheap and popular “shallow-water ship” (*shachuan*), an even more advantageous type of flat-bottomed watercraft. Southeast Asian shipbuilders also provided technical innovation. The outcome was the ubiquitous junk (a word probably originating in Javanese, but later applied mainly to Chinese ships) that shaped European perceptions of the Asian maritime world.

Extended trading networks covering the South China Sea came into being as a result of two developments occurring in the fifteenth century. First, the Chinese government dispatched several huge fleets under Admiral Zheng He (c. 1371–1435) to establish contact with numerous countries in Southeast Asia and on the Indian Ocean. Although this policy was soon discontinued, several of the links formed by these naval missions were maintained as “tributary” relationships, in which ritual, diplomacy, and commercial interest interacted in a complicated way. The best example of a tributary relationship with a strong economic content is the Sino-Siamese (i.e., Thai) tributary trade, conducted officially between

the Siamese royal court and imperial representatives in South China. Its material underpinnings were the complementary structures of the two economies: Siam produced rice that was needed to feed the rapidly growing population of the southern provinces of Guangdong and Fujian. The Chinese demand for rice, in turn, was partly the result of the conversion of rice paddies into fields for cotton, tea, and mulberry trees for silk, all commodities used at home and in trade. In the opposite direction, Siam imported copper from mines in the Chinese province of Yunnan. This trading pattern persisted up to the middle of the nineteenth century.

Second, emigration from Guangdong and Fujian seems to have increased during the fifteenth century. Chinese merchant communities settled in various parts of insular and continental Southeast Asia. They were viewed with suspicion by the Ming dynasty, and after the Chinese authorities restricted maritime commerce much of their trading activity was considered illegal. This did not prevent a flourishing trade in spices, silk, timber, skins, gold, copper, tin, medicinal materials, and other valuable goods. Apart from Chinese merchants, many local groups, Arab traders, Indian businessmen (many of them from Gujarat) and even Japanese ships were involved in these commercial transactions, often ultimately driven by demand in an increasingly prosperous Chinese market. The famous pepper trade to Europe, for example, found its equivalent in vast exports of pepper from Sumatra and other islands to China.

The arrival of European ships changed the established trading patterns within the region without overturning them. The Europeans' main advantage lay in the size and armament of their ships (although Zheng He's exploring fleet compared favorably to those of his European counterparts). After a brief period of intrusive violence, the Portuguese understood the wisdom and even the necessity of partially adapting to Asian trade. The Dutch and later the British developed their own forms of "country trade," conducted by European trading firms along intraregional trading routes. European traders were closely dependent on indigenous producers, merchants, and providers

of credit. Long-distance trade to Europe remained in the hands of the European chartered companies. While the East India Company (EIC) preferred direct contact with Chinese merchants in Guangzhou (Canton) and other South Chinese ports, the Dutch *Verenigde Oost-Indische Compagnie* (Dutch East India Company, or VOC) relied on Batavia (present-day Jakarta) as its central emporium and collecting point in the East. Thus, Batavia served as a link between the various Eastern networks and the transoceanic shipping routes.

There is little statistical evidence for the scope of trade in the China Seas in the early modern era. Data on maritime customs revenue collected at ports in South China, however, indicate that the volume of trade multiplied between the sixteenth century and the 1820s. The expansion of foreign trade facilitated regional specialization all around the China Seas and thus had a profound effect on economic activity in the entire region. The rise of port cities, with their cosmopolitan communities of sailors and traveling merchants, contributed significantly to social differentiation. Yet there was no steady progress of opening up to the world. Japan's Tokugawa shogunate, the military government in power from 1600 to 1868, drastically curtailed Japan's foreign trade with all possible partners from the 1630s onwards, and while Chinese maritime commerce flourished after about 1720, many noncolonial entrepôts in Southeast Asia lost their dynamism at roughly the same time. Trade in the China Seas not only constantly changed its patterns in space, but also went through long-term as well as short-term cycles of expansion and contraction that were partly driven by political and military factors, as the market economy of maritime Asia in early modern times operated under conditions set by rulers and states.

Treaty Ports, Steam Shipping, and the World Market

The "opening" of China and the establishment of the earliest treaty ports (ports designated by treaty for trade) in 1842 was soon followed by the

introduction of steam shipping into Chinese coastal and riverine traffic. Steamers possessed advantages that had a deep impact on trading patterns. Their carrying capacity was far greater, they could easily operate on the sea as well as on major rivers, and their deployment could be organized by large-scale capitalist enterprises. In the China Seas, especially in the south, sail and steam continued to coexist for more than a century. The most dynamic lines of business, however, were captured by modern forms of transport.

From the 1820s through the 1870s, China's foreign trade was dominated structurally by illegal and, from 1858, legalized shipments of opium from India to China. This trade used the South China Sea for transit, but hardly affected Southeast Asia, where different networks of drug trafficking existed. An important change came with the economic development of the European colonies in that part of the world during the last quarter of the nineteenth century. The introduction of large-scale plantations and of mechanized mining as well as the intensification of peasant production for export integrated Southeast Asia much more closely into the world economy than ever before. Expatriate entrepreneurs of Chinese origin were instrumental in forging these connections. By this time, an overpopulated China became a supplier of cheap labor. Chinese emigrants took advantage of the agricultural and mining opportunities in insular and continental Southeast Asia and beyond. The migration of contract labor from southern China to various overseas destinations, termed "coolie trade" by contemporaries, was largely organized by Chinese recruiting firms, although transport remained in the hands of European-owned steamship companies.

It was a structural hallmark of Chinese foreign trade between the First Opium War (1839–1842) and the establishment of the People's Republic in 1949 that indigenous shipping companies secured a substantial share of the market in coastal and inland transport, but never succeeded in entering overseas shipping. China's lack of a merchant navy was symbolic of the country's subordinate position in the international

economy. Another new feature in the early twentieth century was incipient industrialization.

The Fall and Rise of China's Maritime Commerce

The Great Depression of the 1930s along with Japanese aggression against China and the Western colonies in Southeast Asia put a severe strain on the trading networks in the region. Exports of conventional commodities declined sharply during the Great Depression, when demand fell in Asia, Europe, and the Americas. Chinese emigration, formerly a mainstay of steam traffic in the South China Sea and also between North China and southern Manchuria, went into decline. After the Japanese occupation of Manchuria in 1931, the activities of Japanese shipping companies became ever more imperialistic. The formation of a Japanese-dominated trading sphere known as the "yen bloc" was a bid for autarky and protected export markets. In the early 1940s, the Japanese restructured large segments of long-distance trade according to the needs of their war economy. The Pacific War itself was caused in part by economic factors, such as the United States' petroleum embargo against Japan, put in place in July 1941, which made it clear to the Japanese that a self-sufficient empire unaffected by the world market was an impossibility.

The collapse of the Japanese Empire in 1945, the Chinese revolution of 1949, and the disappearance of European colonial rule in Southeast Asia after the end of World War II ruled out a return to prewar patterns of maritime commerce. Only Hong Kong survived as a first-rate emporium, now with a considerable industry of its own. A large part of the People's Republic of China's trade with Southeast Asia and Europe was channeled through Hong Kong. At the same time, the Communist government in China began the long-term process of reestablishing China's lost military sea power and mercantile presence in the China Seas and on the world's oceans. China's stated intention of acquiring an aircraft carrier is a serious indication of its intent to become a major maritime and naval

power capable of maintaining a presence and projecting that power well beyond China's shore.

In respect to trade, the China Seas remain a very significant and geostrategic body of water. With the rise of China as a major exporter of manufactures to the world, the establishment of a free trade agreement between the Association of Southeast Asian Nations (ASEAN) and between China and ASEAN, the China Seas remain one of the world's busiest sea lanes.

Trading Patterns, Eastern European

To understand trading patterns in Eastern Europe it is useful to examine the East–West divide of Europe that had its roots in the ancient and premodern world. With post-Communist globalization of trade, and the increasing exchange among European Union members in the twenty-first century, there is little reason to consider Eastern Europe as a distinct trading region.

If civilization means thinking about and acting toward “aliens” civilly, then globalization means thinking about and acting toward potential partners globally. Both concepts come into play when discussing European regional economic relations, which embody aspects of mutual alienation—here “alienation” is used in its original, general sense of being “other,” the Latin *alius*—especially between East and West.

The concept of “otherness” that divided Europe in terms of geographic longitude originated in two major “unifications” of classical times (the Greek Empire of Alexander the Great and the Roman Empire) and in two major, subsequent divisions (the split of the Roman Empire into a Western Empire ruled from Rome and an Eastern Empire ruled from Byzantium, and the Great Schism of 1054 between the Roman Catholic and the Eastern Orthodox churches). Both empires thus considered the rest of Europe as “other” from themselves, and the two divisions made Eastern “other” to Western, and vice versa.

Early East–West Trade

Whereas the boundaries separating “east” from “west” depressed trade and barter, the later religious division—the “north” remaining Christian and “south”

becoming Islamic—initially stimulated trade. The explanation lies in cultural asymmetry, be the boundary longitudinal or latitudinal.

In its crudest form the cultural divide was language, merely because that of the “other” was incomprehensible: Greeks and Romans called foreigners *barbari*, “barbarians,” parodying their tongues as *bah bah*; Slavs described foreigners as *nemets*, from the verb *nemet*, “to become dumb”; Russians and Poles later restricted the word to Germans (*nemtsy*; *niemcy*), paradoxically the nation with whom both political confrontations and economic exchanges were greatest. The cultural, political, and economic development of the “west” was more advanced than that of the “east” and tended to limit trade to the “western” import of raw materials and agricultural and hunting produce against its export of manufactures. Thus the treaty of 944 between Prince Igor of Kiev and Byzantium—the first formalization of east–west trade—imposed quotas on the quantity of silk goods that the *gosti*, or traders, of Kievan Rus could purchase annually. Although Suzdal succeeded it as the Russian capital in 1169, Kiev was (until conquered by the Mongols in 1240) one of Europe’s largest trade centers, a “Ravenna of the North.”

A reverse asymmetry was obtained across the north–south division of the Mediterranean and western Asia. Byzantium, and Europe generally, bought metal goods and textiles from networks spanning Alexandria and Damascus to Bukhara and Samarkand, cities that in the Middle Ages were more industrially advanced than those of Europe. The Silk Roads from Europe to Central Asia, along which Chinese, Persian, and Indian manufactures flowed, became the major channel of east–west trade when piracy

Tatar conquests lead to a far-reaching trade. Pictured in this illustration from a 1655 book by Martino Martini are treasures from several cultures collected in a cave. Beinecke Rare Books and Manuscript Library.

impeded use of the sea passages and Ottoman Turks blocked Christians from the southerly land routes. But by the time Marco Polo publicized the route's commercial attractions, cities in his native Italy were creating new forms of enterprise and new products in a proto-industrialization that would by the eighteenth century eventuate in Western economic superiority over the East.

Medieval Markets

Meanwhile, however, Russia had succumbed to the Mongols. Already controlling China, Persia and Transcaucasia from their Central Asian base, Tatar armies arrived on the Volga in 1236 and by 1240 had conquered most of the Russian principalities, which for two centuries thereafter paid tribute to the Khans of the Golden Horde. The command economy imposed by the "Tatar yoke" (*tatarskoe igo*) influenced the Russian administrative and fiscal structure—the present Russian words for customs house, label, money, and treasury derive from Mongol. The command economy itself was to return, albeit in modern and more complex form, in the Soviet system of 1918–1991. The

Republic of Novgorod resisted the Tatars and became the commercial capital of Russia: until the establishment of Saint Petersburg in 1703, the Novgorod Fair was the epicenter of east–west trade.

From the twelfth century the institutional setting for overland trade in Western Europe was the annual fair (*Jahrmarkt* in German), though its equivalent in Russia, derivatively the *yarmaka*, did not appear until the sixteenth century. German, Scandinavian, and Greek traders presented their goods for sale, which were purchased by Russian *gosti*, who supplied farm and forest products in return, organizing supply chains that for fur pelts stretched for more than a thousand kilometers. Merchants organized as the Hanseatic League were the most important Western mercantile community, while the Russians grouped themselves by sources of imports—*stetichniki* trading with Stettin, for example, or the *gotlandsky dvor* with Swedes. For the rest of medieval Eastern and Central Europe, the Frankfurt Fair was the cynosure among many regional fairs, convened around the feast day of locally venerated saints. Seaborne trade remained in the hands of foreigners, Venetians and Genoese in the Mediterranean and the Black Sea, and English

A fabric merchant in Samarqand, once the “dividing line” between East and West on the Silk Roads and a center of Islamic study, displays silk, cotton, and wool fabrics, as well as carpets, circa 1910. Photo by Sergei Mikhailovich Prokudin-Gorskii.

to the White Sea, whence Russian forests provided exports directly as timber, and indirectly as charcoal for smelting copper and iron and as ashes for bleaching linen.

Trade Between Modern Nation-States

The transition from medieval to modern statehood in Europe is conventionally dated at the Treaty of Westphalia in 1648, though the fiction of Europe's Holy Roman Empire was not to be terminated until Napoleon's fiat of 1801. Nation-states became economic as well as political entities, limiting by taxes, duties, and bans the trade of their citizens with others. Thus long globalization of Christian Europe ended—in the sense that within its area a trader could choose globally among potential partners. The largest state on the eastern side was, of course Russia, and its trade relations were transformed by Peter the Great (1672–1725). His visits in 1697 to his Baltic provinces, Prussia, Hanover, the Netherlands, and England provided the czar with models for far-reaching administrative and fiscal modernization and the encouragement of

trade and industry. The creation of his “window on the West,” Saint Petersburg on the Baltic Sea, and territorial expansion along the Black and Caspian Seas fostered commerce. Trade across the Pacific, however, had to wait for the founding of Vladivostok in 1860 and the construction of the Trans-Siberian Railway in the ensuing decade. Financial intermediation was internationalized by the opening of the Petersburg stock exchange, the Bourse (Birzha), in 1703, and by 1914 there were 115 stock and commodity exchanges across the country. Nevertheless it was not until 1897 that Russia went on the gold standard, only to suspend convertibility at the outbreak of World War I in 1914.

Between 1648 and 1914 the only large state of Eastern Europe was Poland until its dismemberment by Russia, Prussia, and Austria at the end of the eighteenth century. In the Balkans, Montenegro clung to a precarious autonomy throughout, with little to export save bandits; in the nineteenth century, Bulgaria, Romania, and Serbia gained their independence, but, being small and agrarian, their impact on European trade was negligible. Serbian pigs were herded to

My vision is that our country [Kosovo] should be integrated in the EU, to transfer a part of our independence there. It is also our duty to do it, if we want to establish trade and a sound economy. This is the vision that I am working on and I will continue to work in the future. • **Ibrahim Rugova (1944–2006)**

Austrian slaughterhouses, Bulgarian attar of roses and tobacco had niche markets, and in the later nineteenth century tankers shipped Romanian oil up the Danube. German occupation of much of the region during World War I nullified frontiers, but within a controlled *Kriegswirtschaft* (war economy) there was scant trade to flow across them.

Post-Habsburg Europe

The leitmotif for Eastern Europe in the Versailles and Trianon peace treaties (1919, 1920) was national self-determination: Poland and Albania were reborn; Hungary, Czechoslovakia, and parts of a new Yugoslavia were separated from the Austro-Hungarian Empire, as was Transylvania, to enlarge Romania. Soviet Russia after Lenin's 1917 revolution lost territory to Poland and Romania. The immediate economic damage of the new frontiers was the disappearance of the Austro-Hungarian customs area: at the Portorosa Conference (1921) the successor states negotiated a set of protocols that could have restored a low-tariff basis, but governments never ratified them, and by the time of another failed attempt, the Geneva Conference of 1927, mutual tariffs were 39 percent of price. The reason lay in the smaller states' fear of economic and financial domination by Budapest and Vienna: Czechoslovakia, Romania, and Yugoslavia were concerned lest Hungary reinstate itself territorially or commercially. Nevertheless the foreign trade turnover of all seven, like that of the USSR (the title formally adopted by that nation in 1924) during its New Economic Policy (1921–1928), expanded during the 1920s. The reverse was true of the 1930s. The industrial exports of Czechoslovakia and Poland were worst hit by the world depression after the 1929 stock market crash, but all of the countries concerned lost export earnings as raw material and agricultural prices collapsed. Over the two interwar decades most countries exported only one-tenth of their national product (but almost double that in Czechoslovakia and Hungary), while after 1928 the Soviet Union retreated into near autarky under Stalin's five-year plans (by 1937 it exported only 0.5 percent of an enlarged

national product). The Eastern European reaction to the depression, as elsewhere in the developed world, was to erect higher protective tariffs and restrict currency convertibility. Apart from Czechoslovakia, which was a net capital exporter in the 1920s, the region borrowed substantially from Western Europe, but creditor-currency devaluation and the shrinkage of financial markets brought the ratio of the Eastern European countries' external debt down to 18 percent of GNP by 1938. Overall, the interwar years were an abnegation of regional globalization.

Already before World War II Nazi Germany had imposed a Reichsmark clearing system on its Eastern European trade partners except for Poland; this at least assured them of markets in a depressed world, but Germany's rearmament left few goods and services upon which they could spend otherwise inconvertible balances. In essence they were financing that arms drive. Beginning with the annexation of Sudetenland from Czechoslovakia in 1938, German (and in the Balkans, Italian) occupation policies, and those of its client states, subordinated Eastern Europe to German economic requirements, formulated as a *Grossraumwirtschaft* (the economy needed to support German territorial expansion). The region, and the western USSR after the 1941 invasion, were to be tributaries of farm produce and raw materials to a German "core" of heavy industry, into which only the German "protectorate" of Bohemia-Moravia was economically incorporated.

The COMECON Era

Eastern Europe endured a further occupation when the Soviet armies swept to victory in 1945. By 1947 the governments of eight states were under Communist rule (Albania, Bulgaria, Czechoslovakia, Hungary, Poland, Romania, the USSR, and Yugoslavia), and in 1949 the USSR adapted its Zone of Occupation in Germany into the German Democratic Republic. If the decisive break with the Western market economies is to have a date, it would be 1947, when the Soviet Union and its subordinate states rejected participation in the Marshall Plan and in the ensuing

A busy Russian port, 1677. From a book by Balthasar Coyet, published in Amsterdam. Beinecke Rare Book and Manuscript Library, Yale University.

Organization for European Economic Cooperation. In ostensible compensation for the absence of a corresponding body for Eastern Europe, the USSR sponsored the establishment of a Council for Mutual Economic Assistance, commonly abbreviated to COMECON, in 1949. By then Yugoslavia had broken with the USSR and Albania had changed allegiance from Yugoslavia to the Soviet Union. COMECON included Albania briefly in its membership, and later two other Soviet allies, Cuba and Mongolia. In the 1950s and 1960s a steady 60 percent of members' exports were directed to each other—exports predominantly of Soviet raw materials against Eastern European equipment and manufactures. Trade was underwritten among COMECON members by a mutual coordination of annual and longer-term plans for each economy, and trade with the West deterred by strategic embargoes and restrictions imposed by NATO members through a Consultative Group Coordinating Committee (CoCom). As the imperatives of the Cold War weakened and estimates of comparative trade advantage strengthened, the mutual export

dependence among COMECON nations diminished: by 1980 it was 49 percent and by 1990, 38 percent.

Post-Communist Globalization

The collapse of communist regimes in all COMECON states between 1989 and 1991 brought the Council to an end and opened the trade of the twenty-seven countries of Central and Eastern Europe and the Commonwealth of Independent States (CIS) to worldwide globalization: by 2002 only 21 percent of their exports moved within the region, while 73 percent were to other developed market economies (6 percent were with developing countries). Capital from the West supported economic development. Foreign direct investment amounted to \$34 billion in 2002; gross external debt was in aggregate 46 percent of Eastern European GDP with 44 percent of that in the CIS alone. All but three countries (Belarus, Turkmenistan, and Uzbekistan) had by 2003 liberalized trade and current payments, and all but those three and six others (Azerbaijan, Bosnia-Herzegovina, Kazakhstan,

Russia, Serbia-Montenegro, Tajikistan, and Ukraine) had joined the World Trade Organization. Once it had been opened to commercial and financial flows like those of most developed economies, scant rationale remained for considering Eastern Europe as a distinct trading region. As the European Union extended its membership—the Czech Republic, Estonia, Hungary, Latvia, Lithuania, Slovakia, Slovenia, and Poland joined in May 2004; Bulgaria and Romania joined on 1 January 2007; Croatia, the former Yugoslav Republic of Macedonia, and Turkey are candidates to join, while Albania, Bosnia and Herzegovina, Montenegro, Serbia, and Iceland are recognized as potential membership candidates; Kosovo is also seen as a potential candidate, but not all member states recognize its independence from Serbia—what had once been trade between blocs became the internal trade of a single market or trade with countries, both east and west, having association agreements with the EU. Thus, perhaps, the concept of “other” (alien) will give way in a market of globalized trade to a truly civilized exchange.

Trading Patterns, Indian Ocean

The seas, gulfs, and straits of the Indian Ocean have been areas of intense trading activity from the beginning of human seafaring. The unique nature of its wind patterns enabled the development of maritime trading, linking it to the Atlantic, the South China Sea, and the Pacific. Today the Indian Ocean incorporates those regions that together trade in the bulk of the global oil, which has always been a maritime commodity.

The physical features of the Indian Ocean have fundamentally shaped the development of trading patterns in the region throughout history. Historians offer different perspectives on the chronology and regional boundaries of Indian Ocean trade depending on their vantage points, but the basic elements of states and empires, navigation and mapping, goods and services, and transportation technologies need to be taken into account in any long-range analysis of trading patterns in the Indian Ocean.

Geography and Climate of the Indian Ocean

The Indian Ocean is the site of the most ancient and complex maritime migrations and trading networks of all Earth's oceans. Covering an area of over 73.4 million square kilometers, extending approximately 6,400 kilometers at the equator and more than 9,900 kilometers at its widest point from the tip of southern Africa to the west coast of Australia, the Indian Ocean is the smallest of the three major global oceans. It is bounded on the east by Africa, on the north by Asia, on the west by Australia and on the south by Antarctica. Twenty-six continental nations

have coastlines with access to the Indian Ocean. The Indian Ocean is home to four island nations and three archipelagic nations. It has more major rivers flowing into its waters than any other ocean, and these river outlets have been essential to the ebb and flow of trading networks. The Zambezi and Limpopo enter the ocean in Mozambique; at the border region of Iraq and Iran, the Tigris and the Euphrates meet at the confluence of the Shatt al Arab near the coast; in Pakistan the Indus meets the ocean; and on its path through India the Ganges meets the Brahmaputra to create the delta region of Bangladesh. The Irrawaddy flows through the length of Myanmar (Burma) to the waters where the Bay of Bengal meets the Andaman Sea. This complex network of rivers and coastal regions that connect inland to ocean have been as essential to trade as the ocean itself.

The seas, gulfs, and straits of the Indian Ocean, including the Red Sea, the Persian Gulf, the Arabian Sea, the Bay of Bengal, and the Strait of Malacca, have been areas of intense trading activity from the beginning of human seafaring. But it is the unique nature of the Indian Ocean wind patterns that have enabled the development of maritime trading patterns, and linking it to the Atlantic in the west and the South China Sea and Pacific Ocean in the east. Although the advent of air traffic has altered the global networks of trade, the complexities of interaction in the Indian Ocean have not diminished. The trading patterns of the Indian Ocean link the most populous regions in the world. Moreover, the Indian Ocean incorporates those regions that together constitute the bulk of the global oil trade, which has always been a maritime commodity.

The earliest maritime technologies were based on sailing craft that by nature depended on the vagaries

Historical drawing of Zanzibar, and island off the East Coast of Africa, as seen from the sea.

of wind patterns and ocean currents that carried the vessels across the sea. Absolutely basic to any long-term historical analysis of the Indian Ocean is a consideration of the monsoon winds. The Indian Ocean is unique in having a seasonal pattern of winds that facilitate transoceanic shipping. The monsoons are caused by differences in the temperature of air above land and sea, which generate wind that blows from cold to hot regions. In the Indian Ocean the biannual monsoons blow from the south and west during April through August, reversing direction between December and March. Seasonal patterns of high and low rainfall correspond with these winds to varying degrees outside the equatorial regions, although in peripheral areas the impact on rainfall is minimal. The word *monsoon* derives from an Arabic word, *mausim*, and the Arabs, Indians, and Persians called the Indian Ocean area “the land below the winds” in recognition of the importance of these wind patterns.

The second major wind pattern is the trade winds of the southern Indian Ocean that occur between latitudes 10° and 30° south and that blow consistently from the southeast. This trade route directly across

the breadth of the Indian Ocean was not commonly used before seventeenth-century European traders entered these waters from the Atlantic.

Early Mariners

The Indian Ocean was probably the first ocean traversed by mariners. Technologies of seafaring developed in the first human coastal settlements, whose inhabitants relied partly on fish for their subsistence. Various delta and coast-hugging maritime networks existed from the earliest known times. The regional networks of the Red Sea and Arabian Sea, the East African coast, the coasts of South Asia, and in the archipelagic regions of Southeast Asia developed their own patterns of maritime trade and technology.

The Egyptians and Mesopotamian civilizations traded along the coastal networks of the Red Sea and Persian Gulf over 7,000 years ago, but their maritime voyages did not extend into the open ocean. Inland trade was far more extensive than maritime trade during this early period.

Southeast Asian seafaring evolved as people migrated from the mainland and established the first

human settlements in the vast Indonesian archipelago. Linguistic and archaeological evidence suggests that Austronesian-speaking Malayo-Polynesian mariners from Indonesia crossed the Indian Ocean in their single- and double-hulled canoe outriggers during the first millennium BCE. These ships were stable and fast enough for transoceanic voyages, and the mariners used their knowledge of ocean currents, clouds, stars, and the habits of birds and fish to find their way across the oceans. While these voyages led to permanent settlement, it is probable that the initial incentive was trade.

During this period, oceanic trading links developed between the Persian Gulf societies and those on the northern coast of India. By the time an anonymous Greco-Egyptian trader wrote the *Periplus of the Erythrean Sea* (c. 50 CE) as a guide to trade with the port polities along the length of the East African and South Asian coasts, these trading network was already well established. A myriad variety of luxury goods, including spices, aromatic woods, cloth, ceramics, precious metals, and currency, as well as the forced migration of slaves, constituted some of the items of trade in these Indian Ocean networks.

The Transmission of Religions

Cultural influence accompanied trade in the Indian Ocean, but the region has always been cosmopolitan rather than unified. In the first centuries of the common era, Hindu and Buddhist traders and religious specialists were invited to settle in Southeast Asian polities. The first large-scale states of Southeast Asia adopted and adapted Hindu and Buddhist cultural practices as part of their state formation. One such state was the Srivijaya maritime empire on Sumatra. From its emergence in the seventh century to its decline in the thirteenth, the Srivijaya Empire prospered because of its control of the Malay Peninsula and the Strait of Malacca that linked Asia to China by sea.

From around 1300, transoceanic trading links between the Middle East and South Asia and thence to Southeast Asia helped spread Islam in the Indian Ocean. The foundation of the state of Melaka on the Malay Peninsula and the conversion of its ruler to

Islam both occurred around 1400; Melaka became one of the richest and most cosmopolitan trading entrepôts in the world before its conquest by the Portuguese in 1511. The growth of Melaka and the spread of its influence mark the beginning of the spread of Islam that occurred in parts of the coastal mainland and much of insular Southeast Asia. Meanwhile, on the opposite side of the Indian Ocean the East African Swahili coastal civilizations were expanding, and from the twelfth century onwards they too were converting to Islam.

The First Traders from Outside

The voyages of the Chinese treasure fleet between 1405 and 1433 under the command of Zheng He signal a change in the trading patterns of the Indian Ocean. Zheng He's was the first major fleet that had originated in other oceans to make its way into the networks of the Indian Ocean. The size of the Chinese fleet was unprecedented. Over three hundred large trading vessels and a hundred supply ships manned by some 28,000 sailors and soldiers crossed the Indian Ocean for the purposes of trade and diplomacy. The dimensions and capacities of the largest Chinese junks dwarfed the most advanced European, African, and other Asian shipping technology at the time. Although the direct maritime involvement of China in the Indian Ocean ended with Zheng He, it presaged the arrival of the Portuguese, who made their Indian Ocean debut with the 1497–1499 voyage of Vasco da Gama.

Despite the Chinese and Portuguese forays into the Indian Ocean, Muslim traders of all nations were the major mariners throughout the Indian Ocean during this period. Around 1490, Ahmad Ibn Majid wrote the *Fawai'id*, a famous nautical manual that included detailed astronomical instructions. Over the course of the sixteenth century and through to the end of the eighteenth century, improved maritime technologies and the expansion of trading networks shifted the emphasis from small-scale cargoes of various luxury goods toward bulk trade in spices and other commodities. The increasing pilgrimage trade that brought Muslims from throughout the Indian Ocean

region to Mecca was also a significant component of trading networks.

Historians still argue about the significance of European involvement in the Indian Ocean in the early modern period. It is probable the majority of ordinary people's daily lives in Indian Ocean societies changed minimally, if at all. The entrance of European traders into the region did not cause a breakdown of the complex webs of trading networks. Trade with China through these networks was for centuries more significant than trade with Europe.

The Growth of European Influence

The era of the European chartered companies, which were founded in the seventeenth century, did alter the scope of trading networks by bringing Indian Ocean polities into direct maritime contact with Europe and the Atlantic world. Europeans voyagers had initially come by sea to the Indian Ocean as a consequence of their search for a way to circumvent overland trade routes to the fabled Spice Islands. Once they encountered the rich and varied maritime trade of the Indian Ocean, however, they inserted themselves, often through force, into all the major networks in the region. Indigenous trade and shipping did not disappear but was disrupted with the rapid expansion of commercial capitalism in the region. Although the spices provided the initial impetus for trade, the major commodities that stimulated this commercial revolution were cotton and textiles from India. The European demand for Chinese tea stimulated the production of opium in South Asia: opium was traded in Southeast Asia for the silver and pepper that was traded in China for the purchase of tea.

European weapons technology, one of the few commodities from Europe that was in demand in the Indian Ocean region, altered the dynamics of state formation and conflict. In Southeast Asia, the increasing presence of Portuguese, Dutch, and English trading posts and colonies, established through conquest and diplomacy, fractured many of the existing maritime and territorial empires, which then reconfigured in smaller-scale polities. This era laid the

groundwork for direct European colonization and strengthened imperialist networks that introduced changes in crop production, raw-materials extraction, and commodities production throughout the region. The overall volume of trade increased dramatically, though it continued to be linked to trade with China.

Indigenous shipping was essential to local and regional trade, and new transoceanic trading networks, controlled by European ships, were partly crewed by sailors from all over the Indian Ocean. But indigenous shipping was confined to the Indian Ocean networks. No African, Middle Eastern, or Asian vessels rounded the western edge of the Indian to trade directly with West Africa or Europe.

By the end of the eighteenth century, the scope and scale of Indian Ocean trade had changed dramatically. The Dutch colony at the Cape of Good Hope at the southern tip of Africa made it easier for European shipping to access the Indian Ocean from the mid-sixteenth century onwards. The Cape became part of an entirely new southwestern Indian Ocean regional trading network in which one of the major commodities was slaves.

Plantations and the Expansion of Global Capitalism

Much of the East African coast and the islands of Pemba and Zanzibar came under the rule of the Omani maritime empire around the beginning of the nineteenth century, creating a western Indian Ocean trading network from East Africa to the Middle East and South Asia largely based on ivory, cloves from clove plantations, and slaves. The islands of Madagascar and Mauritius became European slave-plantation colonies, while plantation agriculture grew throughout the region. Tea from India, coffee from Indonesia, and sugar from many Indian Ocean societies became three of the most significant plantation crops during this time.

In the late eighteenth century, the British had established convict colonies on the coast of Australia. This added another component to trade and forced migration in the Indian Ocean and extended European

This drawing of a village in Malaysia in the nineteenth century depicts Malaysian and Chinese traders.

conquest and colonization to the eastern periphery of the region. In the nineteenth century direct colonization and trade between Europe and Indian Ocean societies intensified. Both South Africa and Australia became dominated by European settlers. Societies in the region became increasingly integrated into, dependent upon, and marginalized by, the expansion of the global capitalism. As the industrial revolution stimulated demand for raw products from around the region, markets were created for European goods, and indigenous production that competed with them was forcibly disrupted. Colonial rubber plantations were established in the East Indies, India, and Ceylon (now Sri Lanka) during the course of the late nineteenth and early twentieth centuries.

Insatiable demands for labor worldwide also created a huge international market for workers that created new networks in the Indian Ocean. While slaves initially provided the main source of labor, gradual emancipation during the course of the nineteenth century stimulated indentured servitude. India in particular became a major source of indentured workers, who were contracted all over the world.

New Patterns in the Indian Ocean Region

The development of European empires and colonies shifted the pattern of major ports and polities in the Indian Ocean over the long term. The earliest major example of this was the displacement of Melaka,

which declined rapidly after Portuguese and then Dutch conquest. The Dutch purposefully diverted trade from Melaka to Batavia (present-day Jakarta) on the island of Java from the mid-sixteenth century. The coastal or near-coastal cities of Bombay (now Mumbai), Madras, and Calcutta became major trading bases for the British in South Asia, while the older inland cities of Delhi in India, Kandy in Ceylon (modern Sri Lanka), and Jogjakarta in Java declined in importance. The intensification of coastal commerce also shifted the emphasis of indigenous state formation, which had formerly been concentrated inland along rivers, toward the coast.

European colonization from the late eighteenth century consolidated this trend with the establishment of port cities such as Penang and Singapore in Southeast Asia, which were entirely the product of British imperialism. Rangoon (now Yangon) became the center of trade in Burma (now Myanmar) under the British, displacing the ancient rice-producing hinterland cities. In East and southern Africa, new ports such as Durban and Lourenço Marques (now Maputo) were founded, while older ports, including Dar es Salaam (in present-day Tanzania) and Mombasa (in Kenya), came under European control.

Technological Advances and Changes

Changes in maritime technology during the nineteenth century profoundly altered the dimensions

of Indian Ocean trading networks. Wooden-hulled ships gave way to iron-hulled ones, but more important was the gradual displacement of the great sailing vessels by steamships that were less dependent on the wind patterns of the Indian Ocean and that reduced the time of voyages. The opening of the Suez Canal in 1869 allowed direct maritime access from the Mediterranean to the Indian Ocean, creating an entirely new network of trade in the region. Steamships had stimulated the demand for coal worldwide, and new mining industries grew up in places like South Africa and Australia. Improved ship design and the development of canning and refrigeration from the late nineteenth century onward transformed the fishing industry in the Indian Ocean from an indigenous and regional trade into an international trade that was part of the global commercial trading networks.

The displacement of steam by fuel derived from oil in the early twentieth century thrust the oil-producing countries of the Indian Ocean into global prominence. By the late twentieth century it also integrated the southernmost territory, Antarctica, into Indian Ocean networks through exploration and possession, if not direct exploitation. The trade in oil is largely a maritime trade and therefore had an effect on the evolution of shipping technology. Purpose-built oil tankers, as well as bulk and oil carriers, currently constitute the largest proportion of shipping vessels in the world. The size and capacity of oil tankers has expanded exponentially since the 1950s, from about 46,000 to 555,000 metric tons.

The advances in airplane technology from the mid-twentieth century, initially stimulated by the intensification of global warfare, have been one of the major motors of globalization. The trading and migration networks of the Indian Ocean have expanded to include air routes. Airplanes have made possible networks that are independent of geographical or oceanic impediments, and the volume of both cargo and passenger air traffic in the Indian Ocean continues to grow rapidly. Airplanes enable people to travel faster and further than any other form of transport, stimulating migration and tourism as major economic factors throughout the Indian Ocean. Although indigenous shipping technology has not entirely disappeared in

the Indian Ocean, it has been marginalized by these transportation innovations.

From the End of World War II to the Present

By the end of the twentieth century all the nations of the Indian Ocean had gained independence from colonial rule. World War II was an important stimulus to this trend and marks a turning point in the region. Britain and the Netherlands were focused on the European war at the expense of their colonies. Communication between Europe and the Indian Ocean was disrupted, while in Southeast Asia the expansion of the Japanese Empire included the conquest of Singapore, Indonesia, and Burma, and the replacement of colonial regimes by nationalists. Indian nationalists demanded independence; the result was the partition of India into the independent nations of India and Pakistan in 1947, followed in 1971 by the creation of Bangladesh from the former East Pakistan. African colonies gained independence by the 1970s.

The Cold War changed the geopolitical significance of the Indian Ocean nations, bringing the United States and the Soviet Union into Indian Ocean politics. The Middle East oil-producing states became a global focal point, and nationalist governments were closely monitored. Global geopolitical networks such as the nonaligned movement, which was inaugurated in Indonesia in 1955, attempted to establish an alternative to Cold War allegiances for newly independent states. The Organization of Petroleum Exporting Countries (OPEC) was founded in Baghdad in 1960 as a global organization for oil-producing countries that had hitherto not benefited from the profits of their resources. Middle Eastern states and Indonesia were founding members. Despite the existence of those movements and organizations, the states of the Indian Ocean have not created their own regional body. African States belong to the African Union, formed in 2002 from the dissolution of the Organization of African Unity (1963–2002). Southeast Asian states belong to the Association of Southeast Asian States (ASEAN), which was established in 1967. Processes of globalization continue to accelerate, and

Indian Ocean trading networks can in most cases be incorporated into this trend.

Trading Patterns, Mediterranean

Local and regional sea routes of the Mediterranean were the lifeblood of its islands and coastal settlements from at least the third millennium BCE through to the beginning of the twentieth century CE. Long-distance trade across the length and breadth of its basin has effected considerable and ongoing cross-cultural interaction.

The Mediterranean Sea is a deep geological depression that physically divides three continents, yet since the invention of seacraft it has actually served to foster and sustain a whole range of transcontinental economic and cultural exchanges. Indeed, the Mediterranean and its hinterlands are deemed by historians to form a historical unit. Trade in particular has given the entire region a coherence that allows us to speak of a Mediterranean “world.”

The role of trade has been fundamental. The Mediterranean world was dominated by port cities (e.g., Barcelona, Alexandria, Tyre) or cities with ancillary ports (e.g., Florence-Livorno). Fifth-century BCE Athens and imperial Rome were especially reliant on cereals imported from the Black Sea and North Africa, respectively, and when regular grain sources were threatened, the Mediterranean always provided swift access to alternative sources.

Environmental Features

The Mediterranean has offered a relatively favorable environment for mariners. Compared to the Atlantic Ocean, for example, the Mediterranean enjoys a much milder climate year round, with lighter winds and less turbulent swells. Prior to the advent of mechanized shipping, seaborne traffic was conducted normally

from March through to October, when conditions were milder, and when clear skies and stars facilitated navigation. Winds and currents determined the general pattern of long-distance trade routes throughout the Mediterranean, in which the main current runs counterclockwise around the entire sea basin. The Atlantic, which replenishes 71 percent of annual water loss in the Mediterranean, propels the main current through the Strait of Gibraltar, which moves along the North African coast to the Nile Delta, from where it is forced northwards along the Syria–Palestine littoral. The current continues along the southern European coastline (including the Adriatic) back to Gibraltar. The prevailing winds through the sailing seasons come from between northwest and northeast, which means that sailing ships had to negotiate winds and currents that often ran in opposite directions. Traffic along the northern Mediterranean overcame potential difficulties by sailing between the string of islands from Cyprus in the east to the Balearic Islands in the west. Long-distance trade until the end of the Middle Ages more or less conformed to trunk routes that negotiated the sensitivities of the main currents and winds.

Long-haul traffic appeared to favor the northern littoral. The North African coastline lacks natural harbors and is made treacherous by reefs and sandbanks, but it was utilized heavily by some of the world’s most formidable seaborne powers, (e.g., Phoenicians, Carthaginians, Arabs, Algerian corsairs). In contrast, the northern shoreline is blessed with deep waters and with ample options for safe anchorage. Ships of all sizes could find a dense infrastructure of dockyards, deepwater anchorage, and other port facilities from Gibraltar through to the Levant (the lands along the Mediterranean’s eastern shore).

The Grand Canal in Venice in the 1990s, at one time the major port for Mediterranean trade.

Prehistory and Antiquity

Historians tend to focus on long-distance commercial ventures when dealing with trading patterns, but it was the more localized activities that set the rhythms of Mediterranean economic life. The stir and bustle of even the largest ports, such as early modern Istanbul and Naples, were mainly attributable to the daily comings and goings of localized traffic. Such small-scale trade was mainly characterized by cabotage, the free movement and peddling of small cargo, often along ill-defined and changing routes. Always a cheaper and more efficient option to land transport, cabotage was always responsible for the bulk of total cargo transfers. The vigor and unity of the Mediterranean world probably owed more to the sum effect of such unquantifiable and unpredictable local trade patterns than to large-scale traffic.

Regional-level trade can be traced back to the Neolithic era (perhaps as early as 7000 BCE, from when we can date the first signs of seafaring). Archaeologists have also uncovered remnants of trading harbors that point to the existence of sea-lanes connecting mainland Greece and Crete with Anatolia (modern Turkey). Seaborne exchanges between Egypt and Mesopotamia, via port cities on the Levantine coast, date back to the fourth millennium BCE. Metals and luxury items appeared to be the most valuable trading commodities: Egypt and Mesopotamia exchanged gold and silver respectively. By the Bronze Age (c. 2500 BCE), a sizable seaborne network had emerged. Crete and Cyprus were incorporated into a trading

network with Egypt and the Levant. Minoan Crete and Mycenaean Greece had, by the second millennium BCE, created seaborne trading empires held together by trading colonies in distant parts of the Mediterranean. Mycenaean settlements have been uncovered in Sicily, Sardinia, and mainland Italy.

Bronze Age trading networks collapsed somewhat mysteriously, as did most eastern Mediterranean states and cities, around 1200 BCE. The revival was led by the Phoenicians, who, from about 1000 BCE, built a trading empire that stretched across the length of the Mediterranean. The Phoenicians effectively created the first Mediterranean trading system. Their main interest was securing raw metals from as far away as Rio Tinto in Spain, which they exchanged for craft goods and luxury items manufactured in the Levant. The Phoenicians dominated the sea through a network of settlements and emporia, and trade would serve as the conduit for the dissemination of Phoenician culture, particularly across North Africa and southern Spain. From about the eighth century BCE, belated competition came from the Greeks, who, following the Phoenician model, established city-states and emporia mainly across the northern Mediterranean coastline, and getting as far west as Provence and Catalonia. Greek culture was effectively established along the Black Sea and Anatolian littoral, western Sicily, and along the southwestern Italian littoral.

From the middle of the third century BCE, the center of political gravity in the Mediterranean shifted gradually from the Levant to central Italy. At the beginning of the first millennium CE, Roman legions had already conquered the entire Mediterranean world, making it their own sea (*mare nostrum*). The empire did not function as a coherent economic system, but Roman dominion made changes that were beneficial across the board: piracy was contained, merchants operated under one legal system, and the Romans established a fully monetarized economy. Marine archaeologists suggest that the relatively large number of discovered shipwrecks that date from 100 BCE to 300 CE point to trading activity on a scale that would not be seen again until the late Middle Ages. Ships of between 250 and 400 tons were commonplace, with

The modern market in Athens, Greece, shown here on 2003, overlooks the excavated ruins of the old market (agora).

many servicing the city of Rome's voracious appetite for grain. Much of that grain supply was organized and paid for by the state, otherwise Rome's domestic and interstate trade was the preserve of private interests. Tellingly, the empire's wealthiest and most vibrant cities and territories were located on, or near, the Mediterranean coastline.

For late antiquity and the early Middle Ages, the evidence for Mediterranean trade is patchy and inconclusive. Despite the rapid accumulation of new archaeological data, scholars remain divided over the degree to which the Mediterranean world experienced a prolonged economic depression. Certainly, large-scale trade continued through to the mid-sixth century and did not recover until the tenth. However, it also appears that neither the fragmentation of the Roman Empire, the Arab conquests, the revival of piracy, or plague greatly disrupted the rhythms of localized trading activity, from which the Mediterranean world had long derived its essential vitality. It remained a world of cities, especially Italy and the eastern Mediterranean, for which maritime activity remained as critical as ever. Christian and Muslim pilgrimage to Jerusalem and Mecca was now an additional feature of seaborne traffic. Despite intermittent conflict between Muslim and Christian powers, Christian, Jewish, and Muslim merchants could nearly always be found plying their trade in most Mediterranean port cities. Along the Red Sea and Indian Ocean, the Mediterranean would also remain a vital channel for communications across the Islamic world system.

The Rise of City-States

The eleventh century witnessed the ascendancy of the Italian city-states, especially Venice and Genoa, which led the gradual revival of large-scale seaborne trade. Capitalizing on the turmoil inflicted upon the Muslim and Byzantine worlds by the Crusades (1096–1291), Venice and Genoa secured trading privileges and colonies that provided a platform for Mediterranean trade hegemony. Their highly maneuverable long galleys and heavy cargo-carrying vessels gave them another advantage. More importantly, the Genoese and Venetian states played a significant role in organizing maritime activities, regulating practices, and orchestrating responses to challenges. In the fourteenth century, for example, they oversaw the introduction of a range of cheaper, yet more efficient, galleys and cargo-carrying round ships that counteracted a cost crisis and effectively stimulated greater maritime activity. Moreover, the Italians developed ever more sophisticated means for financing and sustaining ongoing commercial operations; by the fifteenth century large-scale commercial operations were supported by companies and banking institutions (e.g., the Medici family). Until the end of the fifteenth century, Venice and Genoa dominated the movement of material goods, pilgrims, and slaves across the Mediterranean, and formed a vital part of the trade chain that linked Europe with East Asia (via the Silk Roads) and Indian Ocean trading networks.

Domination by the Great Powers

From the sixteenth century, the Mediterranean became a subsidiary of much larger trading zones, especially the Atlantic. The Ottoman Empire and a succession of Christian powers, beginning with Spain, followed by France, Holland, and England, vied for domination, yet none of these powers relied heavily on the Mediterranean for their prosperity. The Mediterranean world had lost its primacy, and historians have been inclined to ignore its history thereafter. The sea, however, continued to nourish the towns and cities of that world, even if life for Mediterranean communities appeared more precarious than ever.

Indeed through most of the early modern period, the Mediterranean seemed to belong to no one. Large-scale Christian and Muslim privateering flourished, as did the slave trade, yet such unsavory operations had always formed part of the Mediterranean redistribution system. The period witnessed the rise of a new kind of port city, such as Livorno and Smyrna, which was relatively free of restrictive traditional trading practices and political authority, which welcomed foreigners, regardless of faith, and which laundered pirate plunder.

By the nineteenth century, the Mediterranean was the subject of rivalries between the great powers, especially following the opening of the Suez Canal in 1869. By the 1880s, British, French, United States, and German commercial and financial interests were investing heavily in the Mediterranean, especially in Egypt and the Ottoman Empire. The burgeoning trade saw the expansion of bustling multilingual entrepôts such as Smyrna, Salonika, Alexandria, Haifa, Suez, and Beirut. Northern Europeans were also traveling more frequently throughout the Mediterranean, especially after the Maghreb had been cleared of corsairs by the 1830s, and by the end of the century bourgeois travelers were visiting the archaeological sites of Egypt, Greece, and Rome in large numbers.

Steam Shipping and Tourism in the Modern Era

Perhaps the most important development in terms of the broader history of Mediterranean trade was the introduction of steam shipping, which had displaced traditional sailing craft by the end of the nineteenth century. Since then, land and air transport have diminished the importance of Mediterranean seaborne exchanges, though mechanized shipping remains important for provisioning island communities and transporting tourists. Oil tankers and luxury cruise liners have become a more familiar feature of the open seas. As a source of wealth, the sea assumed renewed importance through the late twentieth century. In 1973, 60 million visitors enjoyed their summer vacations along the Mediterranean coastline. Numbers

increased dramatically with the establishment of cheap package holidays and the rapid expansion of coastal tourist facilities from the 1980s, and nowadays, coastal tourism is a vital source of income for the Greek, Turkish and Spanish national economies. For the foreseeable future, Mediterranean-trading patterns will be dominated by the traffic in leisure-seeking people.

Trading Patterns, Mesoamerican

Trade and exchange were ancient and pervasive activities throughout Mesoamerica (much of present-day Mexico and northern Central America). The great ecological diversity of Mesoamerica, from steaming tropical forests to highland mountains and plateaus, stimulated the development of regional specialties (such as textiles from the Peruvian Andes) and the opportunity to exchange surplus yields with others.

Trading activities in Mesoamerica (the name refers to much of modern-day Mexico and northern Central America) became particularly prominent with the development of sedentary civilizations, from as early as 1600 BCE. Economic specialization associated with these civilizations required that individuals and communities exchange their specialized production for other necessary goods, while the development of hierarchical social systems encouraged elites to gain access to specific status-linked luxuries, often from distant regions. The production of surpluses also allowed individuals to exchange their excess yields or output for other goods they did not personally produce. These processes became important in the Formative period (c. 1600 BCE–250 CE) and increased during the Classic period (variably 250 CE–900 CE), becoming highly commercialized in the Postclassic period (900 CE–1521 CE). Evidence for trading activities during the Formative and Classic periods relies on archaeological investigations, while rich historical records augment archaeological data for unraveling Postclassic trading patterns.

Types of Trade and Traders

Trade in Mesoamerica was multifaceted: it was carried on over long and short distances; involved producers, professional merchants, and elites; embraced utilitarian goods and luxuries; and took place in marketplaces and royal palaces.

Long-distance trade was typically the domain of the full-time professional merchant. Lacking beasts of burden and a practical use of the wheel, the transport system of Mesoamerica relied on human backs and canoes, and few rivers were navigable. A man could carry up to 20 kilograms with a tumpline across his forehead or shoulders, and could travel approximately 24 kilometers in a day, depending on the difficulty of the terrain. Most trade conducted in this manner over long distances involved low-weight, low-bulk, and high-value commodities such as feathers, precious stones such as turquoise and jadeite, gold ornaments, shells, and decorated textiles. In the Formative period and among the Classic Maya, goods such as these were used by the aristocracy for social and ritual display; this trade was managed by the elites and its focus on elite consumption and control defines it as a “prestige goods economy.” During the more commercialized Postclassic period, Mesoamerican professional merchants served as both state agents and private entrepreneurs. In the Mayan area (present-day southern Mexico, Guatemala, and Belize) they appear to have been of elite social standing, while in central Mexico they emerge as a specialized, albeit ambitious, group of commoners. During the period of the Aztec Empire (1430–1521), such merchants belonged

to guild-like organizations and gained considerable political favor and economic wealth.

Much trade was conducted regionally and involved goods of medium weight, bulk, and value. Produced in specialized regions, these goods were typically carried and traded across ecological zones to areas where there existed a high demand for such goods and materials. The most common products were salt (especially from northern Yucatán), cacao (from coastal and southern lowland regions), rubber (also a lowland product), raw cotton (from coastal regions and inland areas below approximately 900 meters), and obsidian (from specific volcanic outcrops in mountainous areas). These were materials of nearly universal use in Mesoamerica: salt for diet, cacao as an elite and ritual beverage, rubber for the popular ball game and for use in religious ceremonies, cotton for clothing and other textiles, and obsidian as a multipurpose cutting tool and weapon. Some finished goods may also have fallen into this category; these include plain textiles woven of cotton or maguey (fibers from agave plants), paper, reed mats, and gourd bowls. A somewhat different type of commodity, fancy polychrome pottery, also falls into this category, although it was relatively heavy and probably carried a higher value than other goods carried in this manner. Transport of these raw and manufactured commodities was typically in the hands of professional regional merchants, although records from the Postclassic period also indicate that the actual producers sometimes carried their own goods over ecological zones for purposes of trade. The transport involved considerable effort, since nearly all of these goods traveled between lowlands and highlands.

A great deal of trade was carried on by individual producers, most of it over more restricted distances. This type of trade involved most foodstuffs, such as maize and beans, which were heavy, bulky, and relatively low in value; it was inefficient to incorporate such goods in long-distance trading enterprises. Other, similar goods included utilitarian pottery wares and wood products. Individual producers also took advantage of the marketplace setting to sell small lots of regular or seasonal surpluses, such as pottery,

baskets, herbs, fruits, turkeys, and prepared foods such as tortillas and tamales.

Markets

The most pervasive context for trading activities was the marketplace. Every city and community (except for the very smallest) had a marketplace and held a market either daily or on a periodic basis (usually every five or twenty days). It was typically the liveliest spot of the community, where individuals from all walks of life congregated to exchange goods and gossip. During the period of Aztec imperial dominance, the largest marketplace in Mesoamerica had developed at Tlatelolco, also a major residence for long-distance professional merchants. By 1519, Tlatelolco was geographically and politically attached to Tenochtitlán, the Aztec (Mexican) capital city. Reportedly, this market accommodated as many as 20,000–25,000 vendors and consumers daily, while every fifth day it served twice as many people. Being the grandest market in the land, virtually every type of product and commodity, from far and wide, was available there. Other marketplaces were less extensive, serving smaller populations, fewer elite, and more restricted areas. Still other marketplaces became known for their specialties: for instance, lakeside Texcoco was known for ceramics, cloth, and fine gourds; forested Coyoacán focused on wood products and carpenters; the Basin city of Acolman was famous for its dogs; and Azcapotzalco, in the western part of the Basin of Mexico, had a noted market for slaves.

These scenes of bustling economic and social activity were commonplace during the Postclassic, but probably developed earlier. Marketplaces are difficult to detect archaeologically, since markets were often held in an open plaza, and once market day was over, the plaza was swept clean and returned to its original function. Therefore, only vague and spotty information on them exists for Formative and Classic times. A great deal of information on markets and market activities exists for the Postclassic and early colonial periods, however, from historical documents that supplement the archaeological record.

During at least the Postclassic, markets served as the venue for exchanging the full range of commodities produced and manufactured in Mesoamerica. Professional long-distance merchants stopped frequently at marketplaces in their long and arduous treks to and from distant lands, trading local and exotic luxuries to their economic advantage. Regional merchants depended on the numerous marketplaces as they moved their specialized goods across ecological zones. Last but not least, individual producers relied on market days to maintain diversity in their material lives, whether for subsistence or an elevated standard of living. Any given marketplace, then, would see expensive and inexpensive goods, elite and commoner consumers, local and distant vendors and merchants, and familiar and exotic wares for sale.

The marketplace was not only a site for economic transactions, but also for the exchange of the most recent news and rumor. Indeed, under the Aztec Empire, some specialized professional merchants were sent by the emperor to travel from market to market, disguised as local traders; their purpose was to ferret out information on political and military conditions in the region.

The local city-state also benefited from a lively market, as taxes were typically levied on vendors. A different sort of external involvement can be seen at the Tlatelolco marketplace, where professional merchants oversaw the functioning of the market and sat there as judges on market-related crimes and disputes.

Media of Exchange

Trade was facilitated by the general use of specified media of exchange, at least by Postclassic times. The most common and lowest-value exchange media were cacao beans, which may have served as “small change” or to even out unequal values in barter exchanges in marketplaces. While the actual value of cacao beans in pre-Hispanic times is unknown (and probably fluctuated in any event), colonial values may well be fairly representative: two hundred cacao beans for a turkey cock, one hundred cacao beans for a turkey hen, thirty cacao beans for a small rabbit,

three cacao beans for a turkey egg, one cacao bean for a large tomato or a tamale. While relatively low in value, cacao beans were sufficiently valued to have been actively counterfeited.

Large plain cotton cloaks were another common form of money that were higher in value than cacao beans; depending on the quality of the beans and cloaks, values ranged from sixty to three hundred cacao beans for one cloak. Cloaks also served a variety of exchange functions: they could be used to ransom certain slaves, to obtain land, and to gain restitution for theft. A basic standard of living (probably for a commoner) was also expressed in terms of these cloaks, twenty of which could support an individual for one year. These cloaks therefore also served as a standard of value in the economic system.

Other recorded media of exchange were feather quills filled with gold dust in central Mexico, and copper bells, stone beads, and thin copper axes in the more southern reaches of Mesoamerica. Information on all of these forms of money applies to the highly commercialized Postclassic times; it is not clear how extensive such media of exchange may have been in earlier periods. Cacao beans continued as a medium of exchange well into Spanish colonial times, although the other money forms quickly faded away. Spanish coin was used side-by-side with cacao, gradually replacing it.

International Trading Centers

Another significant trading venue was the international trading center. Typically located beyond or at the periphery of major city-states, these centers attracted long-distance professional merchants from great distances. Here, the merchants would find a considerable diversity of trade goods and could carry on a high volume of high-value trade relatively unencumbered by political conditions. While they may have developed early in the prehistory of Mesoamerica, they became particularly significant during the commercialized Postclassic period. Such centers were found throughout Mesoamerica, in highland as well as lowland regions. Wherever their specific locale,

they typically were strategically situated between major polities or significant environmental zones, and were located along convenient trade routes—overland, riverine, or coastal. While on the surface it appears that these trading centers were specialized venues for high-level economic dealings of professional merchants, they were also hotbeds for more regional and locally based trading activities.

Professional Merchants as Private Entrepreneurs

Professional merchants undoubtedly enjoyed a long history in Mesoamerica. They are not specifically documented prior to the Postclassic; however, as early as the Formative period, elite goods such as shells and fine stones traveled long distances. While this trade may have operated by goods passing from hand to hand until they reached their ultimate destinations, their status-linked nature suggests a more centralized, even politically controlled and generated, method of trade. The Classic period witnessed a continuation of long-distance trade in luxuries destined for the elite (again, probably conducted by professional merchants or by the elites themselves) and also saw a growth in exchange of more broadly consumed goods, such as ceramics for cooking, storing, and eating; ground stone for grinding implements; and obsidian for tools and weapons. During the Postclassic, professional merchants attained unprecedented levels of wealth and political influence. In the Basin of Mexico during Aztec times, professional merchants were organized throughout the major cities into their own city wards, or *calpulli*. Resembling guilds, *calpulli* retained exclusive membership rights, a system of internal ranking, a set of specific laws and codes, the ability to manage their own trading ventures and the wealth derived from them, and an advantageous relationship with the state. Professional merchants served the state by carrying state goods on their trading expeditions; they took them as diplomatic gifts to unconquered rulers or used them in profitable exchange negotiations for the state. As mentioned earlier, some of these professional merchants also served the state as spies

in their far-ranging travels. As private entrepreneurs they became wealthy beyond their social standing; as state agents they were esteemed by their rulers but often despised in outlying regions. Indeed, a major motivation for Aztec conquests was the relatively frequent assault and murder of their professional merchants.

Significance of Mesoamerican Trade

Throughout the history of pre-Hispanic Mesoamerica, trade served a number of important functions. It provided a context for evening out ecological and seasonal variations, allowing for households throughout Mesoamerica to obtain a wide variety of necessary or desired goods from distant regions as well as from the local area. Trade was an adjunct to specialization, whereby a specialized producer could be assured of exchange outlets for obtaining other essential commodities. Far-flung trading networks provided exotic and expensive goods to elites throughout Mesoamerica in their efforts to visually enhance their high status. And, in an important general sense, trade served to integrate broad regions in relatively sustained and predictable exchanges of goods, information, and social relations.

Trading Patterns, Pacific

The Pacific Ocean once (and understandably) was perceived as a huge obstacle in the process of exchange—it accounts for one-third of the surface area of the Earth—but it has in fact fostered trade, first in spices, silver, and silks, since the sixteenth century.

The Pacific Ocean comprises over one-third of the surface area of the Earth, is larger than all earthly landmasses together, and equals all remaining oceans/seas combined. The Pacific is double the size of the Atlantic Ocean and contains more than twice the water. Given the Pacific Ocean's magnitude, it is unsurprising that observers traditionally conceptualize it as a colossal barrier to interchange, and regard meaningful and lasting trans-Pacific activity as recent (perhaps post-World War II) and unprecedented. Yet such conventional views are false: crucial trans-Pacific and intra-Pacific interactions have been unfolding since the sixteenth century. Improved navigational technology turned oceans into freeways rather than barriers to interchange. For example, unusually high wages in Gold-Rush San Francisco prompted its affluent residents to have their laundry done in Guangzhou (Canton), China, for a brief time. Control of ports (or at least access to them) has been crucial to Pacific history for centuries.

Spices and the Arrival of Europeans

Islamic traders were already established in Guangzhou, in Gujarat, India, and in Sumatra by the ninth, tenth, and thirteenth centuries, respectively. Melaka, Mindanao, and the Moluccas (the Spice Islands) were Islamic sultanates when Portuguese and Spanish

ships arrived in the sixteenth century. Moreover, three vast Islamic empires—the Ottomans (Turkey), the Safavids (Persia), and the Mughals (India)—served as connectors between Asian Pacific islands and European marketplaces. Venice was the key marketing power for Asian spices entering the Mediterranean basin prior to the sixteenth century.

The Portuguese sought Asian spices. In 1511 Albuquerque conquered Melaka—a strategic hub connecting trade networks of the South China Sea, the Indian Ocean, and the Spice Islands. From this base, the Portuguese subsequently established entrepôts along the coasts of China (Macao in 1557) and Japan (Nagasaki in 1570). Vast networks of Indian Ocean and Asian Pacific exchange predate the appearance of European powers. While Portuguese ships transported perhaps half of the pepper and spices that Europeans consumed during the first half of the sixteenth century, Arabic, Indian, and Malay merchants continued to play an important role in the Indian Ocean trade, shipping spices through the Red Sea, the Persian Gulf, and other traditional routes into the Mediterranean basin.

Spain's imperial presence in the Pacific followed Ferdinand Magellan's crossing of the Pacific in 1521, in search of an alternative route to the Moluccas. Although only one small Magellan ship (of several) finally returned to Spain, its 500,000 pesos in spices generated a moderate profit overall. Thus, Spaniards knew for certain that huge profits awaited future silver shipments from Mexico to the Philippines. Over four decades of frustration followed, however, because powerful westward trade winds and currents thwarted attempts to sail from the Asian side of the Pacific back to the Americas. Miguel Lopez

de Legazpi finally succeeded in 1565 by sailing a northerly route past Japan and then southward down the American coast back to Acapulco, a route subsequently followed by the Manila galleons for 250 years (and followed by ships today in search of fuel economy). Legazpi established Spain's first permanent settlement in the Philippines on the island of Cebu, but abandoned Cebu in favor of Luzon's great natural harbor in Manila Bay in 1571. Embracement of the Chinese junk trade via Manila Bay implied abandonment of the spice trade via Cebu, but the burgeoning silver-for-silk trade generated prodigious mercantile rewards.

Relations between China and the Philippines predate the sixteenth century. Filipino traders had reached Guangzhou by 982 CE. Chinese sources refer to a Philippine maritime raid of a coastal village in Fujian (southern China) in the twelfth century. Filipino ambassadors were received at the emperor Yung-lo's court in 1406 bearing "tribute." Commerce thrived as well among the archipelagoes and surrounding Southeast Asian countries (as well as Japan). Like the majority of the Philippines, "Maniland" was already religiously and culturally Islamic by the sixteenth century.

Batavia, on the island of Java, was established as the headquarters of the Dutch East India Company in 1619. From this strategic position in the Sunda Strait, the Dutch displaced the Portuguese and established dominance over the lucrative spice trade.

Silver and Cross-Pacific Linkages

Tectonic forces endowed mountains around the Pacific's edge—its volcanic "Ring of Fire"—with vast holdings of metals. Earthquakes and volcanic activity are characteristics of these mountain ranges, as well as of the islands and archipelagoes of the Pacific. Much economic and social coherence around the Pacific region stems ultimately from geological history, and nothing influenced trade relations around the Pacific Ocean more—from the mid-sixteenth century to the mid-nineteenth century—than the production and shipment of metals.

Continuous trade between Asia and the Americas did not exist prior to the founding of the city of Manila in 1571. The sudden eruption of substantial direct exchanges between America and China depended upon two industries: Spanish-American silver and Chinese silks. Manila was the linchpin that connected China and Mexico. From Acapulco, Chinese goods were in turn transshipped to Peru and elsewhere in the Americas (and even on to Spain). The first Filipino and Chinese immigrants arrived in America aboard these galleons.

The Manila galleons carried an annual average of 2 million pesos (i.e., fifty tons of silver) during the seventeenth century (voyages that continued until the last galleon was captured in 1815 during Mexico's War of Independence). Manila galleons carried as much silver over the Pacific as the combined shipments of the Portuguese *Estado da India*, the Dutch East India Company, and the English East India Company—major connectors between Asian and European markets.

Merchants of many ethnicities enjoyed high profits: Chinese silks exports rushed toward high silk prices in American markets, while American silver simultaneously rushed toward high silver prices in China. For instance, in 1630 the Portuguese shipped mainly Chinese silks worth 1,500,000 pesos (3,000,000 pesos worth in Mexico), contradicting the common claim that galleon trade declined during the seventeenth century.

Manila's population was diverse: Spaniards of *Intramuros* (the walled center of Manila) were surrounded by segregated populations of Chinese and Japanese, with groups of free and enslaved blacks living in the city. Jesuits organized sodalities for blacks and the local government expelled five hundred free blacks for vagrancy in 1638. Some Manila galleon slaves were sold upon arrival at Acapulco. Africans were sailors on Portuguese ships navigating between China and Nagasaki; they defended Macao against a Dutch fleet and were active in Goa and other Portuguese settlements.

At the main square in Mexico City, authorities established a "Parian" (Chinese neighborhood) where

Utagawa Sadahide, *Western Traders Loading Cargo in Yokohama* (1861). Pentaptych print. Two prints from a five-part series shows an American ship in the harbor with lots of action on the gangplank.

all kinds of products arriving via the Philippines were sold. Trade between Mexico and Peru reflected the vital Manila trade. When a 1634 prohibition blocked Mexican silks from Peruvian markets, Chinese finished silks rose to 90 percent or more of the value of goods traded between Mexico and Peru. Spanish officials traveling in Central America and Peru in the eighteenth century reported widespread sale of Chinese porcelain in Lima and open sale and usage of Chinese silks everywhere from Chile to Panama.

China and the Pacific

China occupied a central role in the Asian and Pacific economy. Large fleets of junks reached Africa and the Middle East during the early fifteenth century. Lack of subsequent European-style trade developments, however, has prompted scholars to blame Chinese state interference for China's failure to modernize during the early modern era. Historical facts do not coincide with this conventional hypothesis. The Chinese economy "silverized" during the sixteenth

century because its paper-money system collapsed, whereupon silver was adopted by merchants for monetary purposes. Subsequent changes in the taxation system reinforced the central role of silver in the Chinese economy. Importation of silver therefore formed the basis of an immense commercial expansion. Despite a lack of official Chinese sponsorship of foreign commerce along European lines, extremely successful Chinese commercial networks emerged throughout Asia during the early modern period nonetheless.

China was the primary demand-side force operating in the global silver market. Silver poured into China via all maritime and land-based trade routes simply because the white metal's price in China was double that of the rest of the world by the late sixteenth century. On the supply side, tremendously rich concentrations of silver were discovered in Japan, Peru, and Mexico beginning in the 1540s, and technological innovation further reduced mining costs. It was this combination—high silver prices in end-market China and cheap production costs in Japan and the Americas—that led to the greatest global mining

Ambition leads me not only farther than any other man has been before me, but as far as I think it possible for man to go. • **Captain James Cook (1728–1779)**

boom the world had ever seen. Acting as intermediaries between the Chinese marketplace and Japanese mines, the Portuguese engaged in highly profitable trade until a 1639 shogunal edict expelled them in favor of Dutch intermediaries (confined to Deshima, a minute islet within Nagasaki Bay). Profits from Japanese silver mines financed Japan's unification under the Tokugawa shogunate by 1600; similarly, American silver-mine profits financed resource-poor Spain's emergence as a premier European power. Both phenomena depended upon high silver prices in the Chinese marketplace. But a century of unprecedented silver imports eventually managed to glut even the giant Chinese marketplace; the price of silver fell and equalized throughout the world by 1640, ending a century-long "Japan and Peru Cycle of Silver" that began in the 1540s. Vanishing profits caused a worldwide trade crisis, and effects reverberated globally for centuries.

Aside from carrying vast volumes of silver and silks, the Manila galleons served as a vector through which American crops were introduced into Asia. New plants such as the sweet potato and peanut were particularly significant because they grew in colder, rocky, and hilly environments like those found in sparsely populated areas of China. Large regions to the north and west could now support relatively dense populations for the first time. Han China's population more than doubled during the eighteenth century and China's territorial size doubled as well, leading to drastic restructuring. Expansion of the Chinese economy implied dramatic increase in the domestic demand for silver one more time. As a consequence, the price of silver in China again rose above that of the rest of the world by 1700 (50 percent higher this time). Reminiscent of the 1540s–1640 silver boom, merchants worldwide once again bought silver where it was cheap and transported it to lucrative Chinese markets. American silver again flooded into China, causing China's silver price to sink to the world silver price level by the 1750s. This time, abnormally high silver-trade profits vanished in fifty years (1700–1750) rather than a century (1540s–1640). The bulk of the silver

entering China during this 1700–1750 cycle came from Mexican mines. Not only were the Mexican silver mines the richest in world history—prior to the Nevada discoveries in the 1860s—but the Mexican peso in particular dominated all silver-money rivals throughout the Pacific Islands, along the Asian coast, from Siberia to Bombay, and indeed throughout North America as well. In 1785 the U.S. Congress declared the Mexican peso (called the "dollar" in Anglo-Saxon countries) an ideal monetary unit for its new nation.

Early Integration of the Pacific

Notwithstanding the conquest of Guam (1662) and the Marianas in the last decades of the seventeenth century, the Manila galleons did not break the Pacific Islands' isolation from the continental Rim. Further integration of the Pacific region occurred between the mid-eighteenth century (end of the Mexican silver cycle) and the mid-nineteenth century (initiation of the "gold period"), when intensified exploration combined with new commercial opportunities. Although Dampier's voyage contributed Australia to the global map as early as 1669, voyages by Bougainville and Cook a century later added Tahiti, Samoa, eastern Australia, New Zealand, and Hawaii to the list of "new worlds" explored by Europeans. Only after Cook's eighteenth-century explorations were many insular Pacific societies meaningfully linked to the world economy. In 1788 a British fleet established a penal colony in Australia.

Although the impact of American plants like maize, potatoes, peanuts, and cassava (the "Magellan Exchange") on mainland Asian societies was immense, the 450 European ships that crossed the Pacific between 1521 and 1769 generated little ecological impact on many Pacific islands initially. Cook's voyages dramatically accelerated impacts on the islands. The first consequence of the European contact was a demographic catastrophe that involved a 90 to 95 percent population decline on many islands; population numbers stabilized

around 1880–1920, and only grew subsequently. Diseases, enslavement, and migration were factors in the decline. Labor migration contributed to the spread of germs around the Pacific. Introduction of new crops and alien species—such as grazing animals, mosquitoes, and rodents—altered island ecologies. Sheep were introduced in Australia and New Zealand for the textile industry. Thanks to the use of quinine (from trees in the Andes) for combating malaria, native or Asian wage laborers were used to develop island plantations that emerged around the Pacific.

Many perceive European voyages and settlements as the main unifying forces around the Pacific, but American and European merchants actually served as middlemen between Chinese markets and Pacific Island ecosystems, which suffered resource depletion on a grand scale. With the exception of whaling, extractive activities were directed to the Chinese market. Sandalwood, sealskins, beche-de-mer (sea cucumber), tortoiseshell, timber, and many other products were exchanged directly and indirectly (via Western manufacturers) for Chinese silks and tea. Sometimes ecological consequences were also indirect, such as when the forests of Fiji were destroyed to provide fuel for drying sea cucumbers for export. Nineteenth-century Hawaiian kings ordered forests torched in order to detect the distinct aroma of burning sandalwood, a product exported mainly to China. All kinds of special products from the Pacific entered the Chinese marketplace directly; or Pacific products could be sold elsewhere in exchange for silver (since China was still the world's largest market for the white metal). Societies isolated for millennia were suddenly linked to world markets with millions of people demanding products from their fragile ecosystems. Scarcity of previously gathered Pacific products after 1850 reduced focus on the Chinese marketplace. American colonists had imported Chinese products since 1700, and merchants from America's East Coast arrived in Guangzhou after the American Revolution. American, British, and Russian seal hunters scoured the America's Pacific coast between 1780

and 1850 in response to demand for furs destined mainly for Chinese, Russian, and European markets. Indeed, the northward spread of Spanish missions up California's coast was a response to southward expansions by non-Spanish fur traders, especially Russians. And by 1800 American whalers and seal hunters were active along the coasts of South America and Antarctica.

The Gold Period

The Pacific's "gold period" began in 1848 with the California gold rush and corresponded with expansion of the U.S., British, Dutch, and French influence on the Asian mainland. Railroad expansion connected interior regions with continental ports, while steamship technologies revolutionized intercontinental commerce. European steamships and powerful new guns were decisive in overthrowing the status quo in Asia. Commodore Perry imposed a commercial treaty on Japan's isolationist Tokugawa regime in 1854 and within a few decades Japan industrialized. Victories over China in 1894–1895, then Russia in 1904–1905 demonstrated Japan's emergence as an economic power, although Southeast Asia was virtually under the colonial rule of the British, Dutch, and French by 1900.

The Battle of Plassey, India, in 1757 altered Asian trade patterns in that the British gained control of Bengal's opium production. Although silver continued as China's principal import, British opium exports to China dominated in terms of profitability. Chinese opium imports rose more than twentyfold between 1729 and 1800. The Chinese emperor Qianlong restricted European merchants to the port of Guangzhou in 1759, where foreigners were allowed to deal only with Chinese firms (hongs) under strict governmental regulation. Chinese exports of silks, porcelain, and tea required import-payment via silver or opium (since there was Chinese demand for little else). Silks were produced elsewhere by this time, and Germany (1709) and Britain (1742) finally mastered production of porcelain. Tea was produced

in quantity exclusively in China, however, until the Dutch (Java) and British (Ceylon and India) developed successful tea plantations at the end of the nineteenth century.

Trade in opium was illegal in China. When Chinese authorities tried to stop it, wars with Britain (1839–1842), Britain and France (1856–1858), France (1884–1885), and Japan (1894–1895) resulted. The Treaty of Nanjing (1842) began a series of unequal treaties that regulated Chinese foreign relations until 1943. China's tributary system was dismantled, Hong Kong was placed under British sovereignty, Chinese ports were opened to commerce, and the opium trade became legal. Britain's trade surpluses with India contributed to Britain's economic strength and to the growth of the Atlantic economy. The British monetary system was based on gold for the major part of the nineteenth century and during some decades of the twentieth. The gold mines of Australia discovered in 1851, the ones in New Zealand in 1861, and exports from India to China provided substantial support for the pivotal role of the City of London in the world financial system.

British activities along coastal China during the first half of the nineteenth century correspond with American expansion in the Pacific beginning with the California gold rush (1848). California became a state in 1850, Oregon in 1859, and Alaska was purchased from Russia in 1867. In 1898, Hawaii was annexed and the Philippines were acquired following defeat of Spain. European powers soon divided China into spheres of influence. In response, United States formulated an Open Door Policy in 1900, which required open trade, territorial integrity, and independence for China. Competition for the Chinese marketplace remained central under such proclamations.

Implications

Often thought of as a “Spanish Lake” between the mid-sixteenth and mid-eighteenth centuries, the world's greatest ocean was exploited with

remarkable success by Iberians (as well as Dutch, Chinese, and other merchants) who controlled key ports providing access to major market areas. From the mid-eighteenth through much of the nineteenth century, numerous nations vied for control of sections of the Pacific. Gold rushes stimulated commercial connections from the mid-nineteenth century. Industrialization narrowed the range of contenders for Pacific supremacy. The Pacific became an “American Lake” after World War II, and American commerce and power remains a dominant force in the Pacific today. It is useful to view the rise of Asian economic powers during the second half of the twentieth century as a reemergence of a centuries-old pattern of response to forces largely emanating from the mainland Asia.

Trading Patterns, Trans-Saharan

Although the Sahara is the largest hot-weather desert in the world, it is not entirely barren, and thus held economic attractions for the populated regions of Africa that surrounded it. Trans-Saharan trade in the global economy flourished in gold and slaves, and camel caravans were ubiquitous until railways and roads diverted most export to the oceans.

From about 800 CE to 1900 the Sahara served as one of the major highways of international trade. For the first seven hundred years of this era, Saharan camel caravans provided the only links between the world economy and major sources of gold and slaves in West and Central Africa. Even after European navigation to the Atlantic coast of Africa broke this monopoly, trans-Saharan trade continued to flourish and even increase, although its global significance shrank. Only in the twentieth century, when colonial railways and roads diverted almost all export commerce to the ocean, did the Saharan trade fall back into its earliest form as a purely local affair.

Early Saharan Trade

At some 5 million square kilometers, the Sahara forms the largest hot-weather desert in the world. It is, nevertheless, not an entirely barren place and held economic attractions very early on for communities in the more populated regions of Africa that surround it—the Mediterranean coast to the north, the Nile Valley to the east, and the western and central Sudanic grasslands to the south. (Note that for the purposes of this article *Sudan* refers to these zones

rather than to the eastern and Nilotic region containing the present-day nation of Sudan.) But the ancient trade in Saharan salt, copper, dates, and some slaves functioned only over short trajectories in and out of the desert, never across its entire north-south expanse. The major barrier was technological: horses, oxen, and donkeys, to say nothing of human porters, could not move efficiently across the great distances between oases, the only sources of water within the Sahara.

When camels were introduced into Egypt and North Africa around the first century BCE, the technological problem of desert transport was solved. Camels can travel for as many as ten days without water while also carrying heavy loads of trade goods as well as provisions for the other members of a Saharan caravan—people and often horses (a major import into the Sudan). Political and cultural problems, however, delayed for many centuries the utilization of this new transport system for regular trans-Saharan trade. When the Berber peoples of the northern Sahara first took up camels, they became more difficult for the Roman colonizers of the Mediterranean coast to control and thus made desert trade between Rome and the African interior more difficult. In the ensuing centuries Roman rule also suffered from internal revolts, invasions by Germanic Vandal traders from Spain, conquest by the Byzantine Empire, and finally, in the seventh century, conquest by Arab armies carrying the banner of Islam. The Arabs were themselves a camel-using desert people, and under their regime the Sahara finally became a route rather than an obstacle to international commerce.

The Catalan atlas, a fourteenth-century map of the world, shows main elements of trans-Saharan trade in its heyday in colorful, late medieval style.

True Trans-Saharan Trade

Even with Islamic rule in North Africa, trans-Saharan trade began somewhat precariously as the enterprise of a dissident Muslim sect, the Ibadis, who exiled themselves to the northern edge of the desert in the ninth and tenth centuries. For more orthodox Sunnis, commerce in the lands of pagan black Africans (*Sudan* is the Arabic word for “black”) was not entirely acceptable. This situation changed in the eleventh century when, under the impetus of the desert-based Almoravid Empire, the Berbers of the western Sahara converted to very strict Sunni Islam and the rulers of adjoining Sudanic states such as medieval Ghana also became Muslims. Indeed, the Sahara then became not only a commercial highway but also a route of Islamic pilgrimage and advanced religious education for devout Sudanis. Along with Muslims, Jewish merchants also played an important role in trans-Saharan trade, although very few of them actually crossed the desert. Instead they formed a chain of settlements linking the northern Sahara to both the African and European sides of the Mediterranean.

Gold

Along with horses, the goods taken by caravans into western and central Sudan included such items as cloth, glassware, weapons, ceramic and metal

housewares, paper, and books. As exports, these cargoes played little role in the international economy, since they were similar to commodities already circulating within the Mediterranean and the volume of items traded was not large enough to make much impact upon Mediterranean commerce or its production base. It was, however, highly significant that for such a low barter price (but at high risk for those who actually crossed the desert) the Mediterranean world could obtain what were then considered quite large amounts of gold (a little more than one ton per annum). Gold not only had value in the Muslim and Christian Mediterranean lands for coinage, jewelry, and storing wealth, but it was also needed to purchase luxury goods from India, Southeast Asia, and China, regions that had little interest in Middle Eastern or European exports.

Gold crossed the Sahara by western caravan routes whose southern termini were towns located in present-day Mauritania or along the northern bend of the Niger river. The actual sources of gold lay considerably to the south of these desert-edge entrepôts around the Senegal river, the southwestern Niger Valley, and the Volta River basin. Camel caravans could not travel into such climates, and Sudanic rulers even discouraged their exploration by North Africans, claiming that the inhabitants were exotic and dangerous savages. In reality there were few cultural differences between the gold-bearing zones and those just south

of the Sahara. However, commerce between them became the monopoly of Sudanic merchants who themselves became Muslims.

Slaves

The other major trans-Saharan export of this era, slaves, came mainly from central rather than western Sudan. The Islamic Middle East and adjoining Christian societies had a great need for slaves to perform household chores, carry out agricultural labor (although never on a scale comparable to European New World plantations), and to serve as military forces. Immediately after the Arab conquest of North Africa many Berbers were forced into slavery, and later a brisk trade in captives supplied the Mediterranean from the Caucasus, eastern Europe, and central Asia. However, sub-Saharan Africa soon became the largest supplier of such human commodities, not only on trans-Saharan routes but also along the Nile Valley and via the coasts of the Red Sea and Indian Ocean.

The total number of slaves who crossed the Sahara between 800 and 1900 is about 4 million. When the numbers transported to Islamic lands by other routes is added, the total comes close to the 11 to 12 million estimated for the Atlantic slave trade, mainly between 1650 and 1850. However, the Muslim trade was not only spread out over a much longer period, it also brought Africans into situations where they were much less segregated from the indigenous population. Almost all African slaves in the Muslim world converted to Islam, and very frequently they were assimilated into local society through either manumission or intermarriage. Descendants of black slaves form a large portion of the present-day North African population and are much less marked than in the New World as a separate social, cultural, or racial group.

Caravans

The caravans that brought slaves and trade goods across the desert, especially from north to south, were often very large, amounting to as many as five

This detail of the Catalan atlas shows a European ship, a camel, and Mansa Musa, the tenth emperor of the Mali Empire.

thousand camels and hundreds of people. They traveled mainly during the cooler seasons of the year, from October to March, and even then moved mainly at night to avoid the intense Saharan heat. Caravans usually assembled at entrepôt towns of the northern Sahara such as Sijilmasa in Morocco, Ouargla in Algeria, or Murzuq in Libya. The journey to Sudanic end points such as Timbuktu (Tombouctou) or Kano took as many as seventy days, traveling at a speed of 24 to 40 kilometers per day. Over the many centuries of the caravan trade, few if any technical improvements were made in this transport system, which was better adapted to conditions in the desert than the wheeled vehicles and instrument-aided navigation that changed land and sea transport in other regions during this time. Nonetheless, movement across such lengthy desert stretches always remained dangerous due to the uncontrollable menaces of sandstorms, attacks by brigands, and the possibility that oasis wells might have dried up or been poisoned since the last visit.

A major trans-Saharan caravan was not a single business enterprise but rather a temporary association of several North African merchants under the leadership of a paid guide. Although the camels were technically owned by the merchants, in effect they

From about 800 CE to about 1500, camel caravans traversing the Saharan desert were the only links between the world economy and major sources of gold and slaves in West and Central Africa.

were rented from desert communities, which also supplied the skilled labor to care for them. On arrival in the Sudan, the camels would be sold. When the time came for a return journey a new, usually much smaller, number of beasts was purchased.

Despite their limited scale and lack of control over their main transport capital, trans-Saharan merchants did make use of quite sophisticated commercial instruments. Thus much of their business was carried on by means of credit, recorded in written documents that accompanied caravans in lieu of currency or any goods that could not to be sold in local markets. As religious learning became more widespread in the Sahara and Sudan, merchants could also extend their range of partnerships beyond individuals with whom they had close personal ties, confident that agreements would be guaranteed by appeal to the extensive commercial stipulations of Islamic law.

The Impact of Atlantic Trade Routes

The European voyages of discovery of the fifteenth and sixteenth centuries opened up a new system of maritime traffic between Europe, Asia, and the Americas that reduced the global significance of all the world's long-distance caravan transport, including the Saharan routes. However, from the perspective of northern and Sudanic Africa, new markets on the Atlantic coast and a general expansion of international trade provided opportunities for economic growth. It is easy to understand why Sudanic societies and the neighboring gold-bearing regions would benefit from sending some of their exports south, but not so obvious why such commerce should also continue

across the desert, given the far greater efficiency of water over land transport in this preindustrial era. The answer lies in the natural protection afforded by the forest zone separating the Sudan from the Atlantic. Travel across that landscape was even more costly than travel in the Sahara, since pack or draft animals could not withstand the disease ecology there and trade goods thus required human portage.

One of the first commodities that Europeans sought on the West African coast was gold. By the fifteenth century the most productive source of this metal within the region did lie near the ocean, in present-day Ghana, which thus acquired its colonial name of "Gold Coast." Europeans managed to divert much of the gold trade away from the Sahara, provoking the sultan of Morocco to launch an invasion of the Sahara and, in 1591, to take over the Timbuktu entrepôt. The Moroccan effort and the still-expanding Sudanic merchant networks within the forest zone assured some continuation of trans-Saharan gold trade. But by the 1800s this commerce had become much reduced and irregular, often constituting no more than a few feather quills filled with gold dust, carried as supplements to other commodities.

In any case, the large amounts of bullion exported from the New World from the sixteenth century onward ended the major role of West African gold in the world economy. For Europeans, the most important export from this region was slaves, who were shipped from the entire Atlantic coast of the continent in huge numbers. However, the demand for labor and military manpower in the Islamic world also increased during the centuries after 1600. Even in its last three hundred years the trans-Saharan slave trade is not

A camel makes an elephant feel like a jet plane. • Jackie Kennedy (1929–1994)

nearly as well documented as its Atlantic counterpart, but as far as we can tell, it increased despite the competition. This complementarity may be explained by the general growth of African populations due to the nutritional impact of New World crops such as maize, cassava, and peanuts. Also, in contrast to the New World slave trade, which generally imported two males for every female slave, Islamic markets for slave labor somewhat favored women over men. European efforts to end the trans-Saharan slave trade provide us with some of our best information on its extent, but they did not become effective until shortly before 1900.

Innovation and Termination

During its last important era (c. 1700–1900), the trans-Saharan trade came to include large quantities of items that had previously formed only a very small percentage of caravan cargoes, such as the hides and skins of goats and cattle, ivory, and, for a brief but very flourishing period in the latter 1800s, ostrich feathers. During this time cities in the western and central Sudan developed their own handicraft industries, which provided Saharan populations with their characteristic blue cotton garments and also produced tanned “Moroccan” leather for export overseas.

This final flowering of trans-Saharan commerce depended upon increased world demand for various consumer goods and the intermediate commodities used in producing them (such as gum arabic, obtained from several species of acacia trees native to the Sudanic region and used in finishing cloth). The driving force of this expanding market was the industrializing economy of Europe and North America. Once Europeans, for reasons having little or nothing to do with trans-Saharan trade, took formal colonial possession of western and west central African territories, new industrial technologies broke through

the forest barrier that had protected desert routes. Railways and later roads now provided the Sudan with direct access to the Atlantic. Despite occasional French fantasies, no rail or road arteries were ever built across the Sahara, where camel caravans still carry salt from desert quarries to the lands of the south.

Transportation—Overview

Human beings keep inventing more and more powerful ways of moving themselves and other things across the Earth and, more recently, through the air and into outer space. Systems of transport defined the range and intensity of contact that local populations had with outsiders; those contacts in turn regulated the frequency with which important new things, skills, and ideas were disseminated.

Changing modes of transportation throughout the millennia allowed wanderers, traders, and missionaries to carry themselves—and innumerable different ideas and things—across the face of the Earth, moving ever further, faster, and more frequently. As transport expanded in range and carrying capacity, it accelerated historical change by bringing new ideas, new skills, and new goods to new places, and tightening the human web of communication that existed from the time language emerged and bands of fully human beings began to spread from the African savannas where they first arose.

Origins

To begin with, human muscles were the only means of transport our ancestors knew. By walking erect and relying solely on leg muscles for locomotion, they freed hands and arms for carrying babies and all sorts of other things. Eventually, human carrying capacity was much enlarged by using pouches tied to the waist, and by carrying heavier objects in slings stretched across the shoulders, using backpacks, and balancing jars on top of the head. But no one knows when or how these adjuncts to unaided human muscles

originated or how they spread. Nonetheless these simple forms of transport continue to exist. Women carrying jars of water on their heads can still be seen in places where pipes do not bring it into their homes, for example. And children carry books to school in backpacks in most modern cities.

A superior cooling system makes human bodies unusually efficient load carriers thanks to our sweat glands. As it evaporates, sweat dissipates body heat far faster than panting does, thus sustaining prolonged muscular effort even under a tropical sun. Vigorous persons can walk up to twenty miles a day even with loads of twenty to thirty pounds. Accordingly, for hundreds of thousands of years, foragers moved about in small bands, carrying everything they needed with them day after day. On festival occasions they met and danced with neighbors and sometimes encountered wandering strangers. Such contacts allowed exchange of rare and precious objects, like razor-sharp obsidian blades, across hundreds of miles. Superior tools and weapons, such as the bow and arrow, also spread very widely by the same sort of occasional contacts and collisions among small wandering bands.

As our ancestors spread across the Earth some bands left tropical warmth behind and had to learn to live in diverse climates. This too provoked invention—clothes for example. But as far as transport was concerned, the really important advance was learning to move across water. Sitting astride a floating log was perhaps the first sort of flotation. But when, where, and how human beings first learned to make and use burden-bearing rafts and boats is unknown. We do know that people got to Australia sometime between 60,000 and 40,000 years ago, and can only

Boats and ships throughout history have transported humans and their material goods. In this drawing from late-nineteenth-century China, two sailboats make their way on the Yangzi (Chang) River.

have done so by crossing about sixty miles of open sea. This required rafts or boats of some sort; and therefore counts as the dawn of human seafaring, even though contact with the Asian mainland was not subsequently maintained.

Movement Through Water

Fishing at sea from rafts and boats was of lasting importance and probably first flourished on the monsoon seas of Southeast Asia. Monsoon winds blow equably for nearly all of the year, reversing their direction each spring and autumn. That made sailing safer and easier than on stormier seas. Fishermen, of course, had to be able to get back to shore with their catch, preferably arriving at the harbor or beach they had departed from to rejoin women and children left behind. In other words, they had to be able to steer and move across or even against the wind and sea or river currents. Various combinations of keel, paddles, oars, and sails eventually made that possible, but all details are unknown.

Yet it is obvious that when controlled movement through water had been mastered, long journeys also became feasible up and down rivers, and by sailing within sight of land, hauling boats or rafts ashore when needing to rest. As a result, navigation by sea and along suitably slow rivers began to match and more than match overland transport, since rafts, dug-out canoes and small boats (sometimes made of animal skins stretched on a wooden frame) carried larger loads longer distances with far less muscular effort than moving cross-country required. But for a long time stormy coasts where high tides prevailed were too dangerous for such navigation. Accordingly, to begin with travel and fishing at sea flourished principally along monsoon coasts of the Indian Ocean, the southwest Pacific Ocean, and the numerous Southeast Asian islands in between.

Domesticated Animals as Transport

Starting about 11,000 years ago, in several different parts of the Earth, people settled down and began to live in agricultural villages. Producing the food they ate by prolonged muscular effort allowed human populations to become far denser than before. They also needed more transport. After all, foragers moved themselves to where their food grew naturally; while farmers had to carry enough food for a whole year (plus seed for the next season) from where it grew to a safe place for storage near their dwelling places. In addition, more and heavier things were worth having when people remained in the same place year round; and some of them—roof timbers, for example—often had to come from afar.

Enhanced need for transport was met when many (not all) food producers began to use the strength of domesticated animals to carry loads. Early farmers in western Asia were particularly lucky in having within their reach a variety of domesticable animals that were useful for transport: cattle, donkeys, horses, mules and camels, Water buffalo in India and Southeast Asia, yaks in Tibet, llamas and alpacas in Peru, and reindeer in the Arctic north were also locally important as beasts of burden, but fell far short of the

capabilities of the animals of western Asia. Accordingly, they eventually spread very widely among other peoples, wherever climate allowed and sufficient fodder could be found.

Donkeys were easiest to manage. By 4500 BCE or before, caravans of donkeys began to traverse western Asia carrying specially valued goods on their backs for hundreds of miles. In the land of Sumer near the shore of the Persian Gulf this overland transport system intersected with rafts and boats moving along the Tigris and Euphrates rivers, and with the long-range coastal shipping of the Indian Ocean. By about 3500 BCE the mingling of peoples, skill and knowledge that this far-ranging transport network created led to the rise of the world's first cities and of what we call civilization.

Later on, horses and especially mules tended to displace donkey caravans in western Asia since they could carry larger loads. Elsewhere, other transport networks—sometimes relying solely on human portage, as in Mexico—allowed other cities and civilizations to arise. They signaled a fundamental departure

from older and simpler forms of human society. Being places where strangers perpetually came and went, and where rules of kinship and local custom could not cope with important everyday encounters, cities, and then states that embraced a plurality of cities, needed new kinds of authority and subordination to function smoothly; managing long-distance exchanges, safeguarding new forms of wealth, and keeping invisible spirits and gods friendly demanded special attention. To meet these needs, a few privileged city dwellers ceased to raise the food they consumed, finding ways to induce or compel farmers round about to hand over part of the harvest to them.

In Sumer and in most (but not all) other early civilizations, priests claiming to know how to please the gods by conducting sumptuous temple rituals were the earliest managers of urban society. Beginning about 3000 BCE, military leaders began to rival them since gathering and defending new forms of wealth required ever-greater effort. Everywhere priests and warriors sooner or later came together and jointly supervised a

transport system that brought large quantities of food and fiber into city storehouses, and used what they collected from the countryside to maintain themselves and to feed specialized artisans who manufactured a multiplicity of objects for the use of professional soldiers and for religious rituals. In Sumer, spinning and weaving wool and dispatching bales of cloth on donkey-back to exchange for items needed to keep soldiers, priests and gods happy—metal, timber, lapis lazuli, perfumes and much else—was especially significant since it kept the cities of Sumer in touch with diverse and distant hinterlands.

The Wheel

Sumerian rulers thus became the managers of a transport network that brought anything of unusual interest or usefulness to their attention from across many hundreds of miles. Wheels, capable of carrying heavier loads with far less effort than before, were among the items invented somewhere within that network, and duly appeared in Sumer where wheeled toys of clay show up a long time before archaeologists have found any traces of actual carts and wagons. At first, wheels were made of solid wood, fixed to an axle that turned underneath the body of the cart or wagon. About 1800 BCE fixed axles and spoked wheels were invented, concentrating friction in well-greased wheel hubs so that pulling heavy loads became far easier than before.

Spoked wheels and hubs made chariots decisive in war, while carrying large quantities of grain, wool, timber, and other heavy commodities on two- and four-wheeled carts and wagons supplied armies and cities much more easily than before. A pair of oxen hitched to a four-wheeled wagon by their horns could pull thousands of pounds across the dry and level landscapes that prevailed in the land of Sumer. But in hilly and wetter places, carts and wagons long remained of little use because they bogged down in mud and could not cross streams.

Other civilizations constructed other transport systems to supply their cities and sustain states and their rulers. Within the Old World, contact by land among

the principal civilizations depended on caravans using one or more of the animals of western Asia. Caravans attained more or less permanent trans-continental linkages after 101 BCE when the Chinese emperor Wudi sent an expedition westward to central Asia looking for a new breed of “blood sweating” horses to use in wars against steppe nomads. He succeeded in his quest, and in subsequent centuries contact across Asia was never broken off for long. Silk, metal, and other precious goods traveling overland between China, India, and western Asia were matched by the spread of ideas, especially the missionary religions, Buddhism, Christianity, and Islam that fitted the human needs of city living. Infectious diseases also spread far and wide along caravan routes, leaving survivors with antibodies in their bloodstreams that were effective against an expanding array of lethal infections.

Caravans had their limitations however, since even a camel, the strongest caravan animal, could only carry about four hundred pounds. Making rough terrain suitable for wheeled vehicles in order to carry heavier loads required building smooth, firm roadways, and bridging streams. That required prolonged and costly effort. Nevertheless, the Assyrian Empire (935–612 BCE) pioneered large-scale road construction. It did so to allow marching soldiers to repel invaders and suppress revolts more quickly. But armies needed supplies from the rear, so merchants used military roads from the start, and long-range carrying capacity by wheeled transport correspondingly increased wherever roads existed.

Later empires, both in China and Europe, also put much effort into building roads. Roman roads are especially well known. They eventually linked the city of Rome with all the provinces except insular Britain, while within Britain local roads linked the productive south with the north, where a garrison defended a wall intended to keep barbarians out. Yet sea commerce across the Mediterranean was far more important for Roman society than anything transported by road. Ships circulated articles of common consumption—grain, wine, salt, cloth, pottery, and much else—among the coastal cities. The Roman roads fed that sea commerce by extending its reach

Mass transportation is doomed to failure in North America because a person's car is the only place where he can be alone and think. • **Marshall McLuhan (1911–1980)**

inland, and also linked up along the northern border with river shipping on the Rhine and Danube Rivers and with the Nile in the south.

Roads during the ancient Chinese dynastic period were less important than those of Rome largely because a network of rivers and canals assured the Chinese government of capacious and cheap internal transport. Empire (935–612 BCE) canals in the Huang (Yellow) River and Yangzi (Chang) basins were initially built for irrigation purposes; but once in place the government could collect taxes in kind from farmers many hundreds of miles from the capital, carrying everything in barges. Sometimes barges simply drifted or sailed down stream, and sometimes gangs of porters had to haul them upstream, pulling on ropes from the banks. That extended navigation far inland; and since such barges carried large quantities long distances very cheaply, they knitted the most densely inhabited regions of China into a single whole much more tightly than anywhere else in the world. Beginning about 1000 CE China accordingly pioneered the construction of a market economy, lubricated by paper money, which embraced ordinary peasants and common taxpayers.

Continental Variations

Elsewhere in the world, the balance between shipping and overland transport varied with topography, climate, and the array of domesticated animals available. In the Americas it is possible that some early immigrants from Asia came by sea, beginning about 20,000 years ago. At any rate, Native Americans were familiar with canoes and rafts long before Norsemen got to Newfoundland, and canoe navigation along the Amazon, Mississippi and lesser rivers was long established when Europeans showed up on the scene to record the fact. The Hopewell and Mississippian peoples of North America, for example, used materials and a few specially manufactured goods that came from hundreds of miles away. Metallic copper from Lake Superior and tobacco pipes were among the objects they carried up and down the rivers of North America. Overland transport among Amerindians

depended on human portage, except in the high Andes of South America where llamas and alpacas supplemented human muscles.

In South America successive empires also constructed an extensive road system in the mountainous terrain of the high Andes that was quite as impressive as that of the Roman Empire. Coastal navigation on the Pacific, in which light balsa rafts played a part, also connected Peru with Mexico in a slender and almost unrecorded fashion; while canoes traveled widely among the islands of the Caribbean as well.

Parts of North Africa shared the caravans and shipping of western Asia; but further south, where tsetse flies made it impossible for horses and cattle to survive, human portage remained the primary mode of overland transport until roads and trucks took over in recent times. Native Australians also relied on human portage entirely. Overall, major improvements in transport continued to concentrate in Eurasia and along its fringes where the overwhelming majority of humankind were already linked by an ever-intensifying web of transport and communication.

Within Eurasia, a striking change came to overland transport when domesticated camels became more common after about 200 CE. These animals were hard to breed successfully; but when the arts of camel management spread from South Arabia, and when a somewhat larger, related species, the two-humped Bactrian camel had been domesticated in central Asia, caravans became far more efficient than before. First of all, camels carried heavier loads than horses and mules. They could also fuel their muscles by grazing on scattered, thorny vegetation in desert landscapes and go for several days without water. Consequently, crossing deserts became possible as never before. All of a sudden, the Sahara in northern Africa became passable; so did deserts in Central and western Asia.

The effect was rather like what happened later when Europeans began sailing across the world's oceans. New peoples and separate civilizations within the Old World, became far more accessible to one another and

exchanges of diseases, skills, and ideas attained new range and rapidity. The most conspicuous result of camel transport was the remarkable speed with which the faith of Islam spread from Arabia across western Asia and began to penetrate India, East Africa, central Asia and, before long, eastern Europe as well. Initial Muslim victories depended on cohesion sustained by their religious faith, but superior logistical support from camel caravans also contributed mightily.

Using camels for overland haulage was cheaper than maintaining roads for wheeled vehicles, so in the Muslim heartlands of western Asia existing roads were allowed to decay and city layouts changed since narrow passageways sufficed for camels. Wheeled transport continued to exist in fringe areas—Europe, China, India and the steppes. But for centuries cheap overland transport on camelback gave Islamic peoples an advantage, especially after they perfected legal systems that allowed camel caravans to move safely through settled regions.

Obviously, desert foraging at night only worked in uninhabited places. Letting camels loose to feed on growing crops was bad business for farmers and merchants alike. Instead, Muslim governments built caravanseries where men and beasts could stay overnight and allowed charitable landowners to escape taxation by dedicating selected estates to supplying free provender for travelers. In effect, free desert forage was thus ingeniously reproduced in agricultural landscapes, reconciling the needs of traveling merchants and their animals with the interests of peasants and landowners. Free food and shelter along the way meant that out-of-pocket costs for caravan transport became surprisingly slender so camels could compete on some routes with ships using free energy from the wind.

Since Muslims shared advances made in ship design until after about 1300, their combination of cheap transport by land and sea was unmatched elsewhere. Muslim traders accordingly became the most successful in the world, operating along the coasts of China and Mediterranean Europe, while penetrating the Eurasian steppes and much of sub-Saharan Africa.

Sailing the Seas

Yet eventually advances in shipbuilding and navigation made sailing on stormy and tidal waters of the northerly Pacific and Atlantic oceans feasible. Thereupon all-weather ships inaugurated long distance transport networks that eventually carried luxuries and goods of common consumption around the whole Earth. Yet it took a long while for all the prerequisites for safe and reliable all-weather shipping to come together. And since wooden boats seldom leave archaeological traces, knowing when and where shipbuilding practices changed is largely guess work.

One breakthrough was the invention of pontoon outriggers to stabilize dugout canoes. These outriggers allowed canoes to carry larger sails and move far faster through rougher seas. Probably as a result, about 500 CE sailors from Borneo crossed the Indian Ocean and settled the island of Madagascar off the East African coast for the first time. Before then, other sailors had moved into the Pacific, and occupied islands as distant as the Solomons. Such lengthy voyages are attested by linguistic affinities between the so-called Malagasy language of Madagascar and languages of Borneo in the East Indies; and by the array of Austronesian languages that range across islands of the Southwest Pacific.

Some centuries later, speakers of Polynesian languages began to cross far greater Pacific distances, reaching Hawaii, Easter Island, New Zealand and some tiny atolls in-between. Exact dates of their arrival are unsure but it seems clear that New Zealand was the last to be settled, perhaps only about 1300 CE. The Polynesian dispersal clearly did depend on sailing canoes equipped with outriggers, and their voyages constitute a surprising accomplishment since finding isolated islands in the immensity of the Pacific was hit and miss. As a result, people on most of the Polynesian islands failed to maintain contact with the outside world until European seamen suddenly intruded on them after 1522.

Austronesian and Polynesian sailing across the southern oceans was matched by increasingly successful ventures across the stormy seas of the

A sailing ship in the style used by fifteenth-century European explorers.

north. Light boats made of animal skins floated buoyantly even on top of big waves; and a keen eye to the weather allowed sailors using such vessels to come and go short distances more or less safely on the northern reaches of the Pacific, Atlantic and Arctic oceans. Inuits, for example, spread around the Arctic shoreline from somewhere in Asia, moving by kayak and dog sled; and learned to harpoon whales from larger skin boats about 800 CE. By that same time, coracles made of cattle skins had carried a few Irish monks to Iceland across the North Atlantic.

But just as navigation across really long ocean distances in the southern seas required outrigger pontoons and larger sails, so the stormy northern seas could only be regularly crossed by building larger ships that cut through the waves rather than riding lightly on top of them. In the North Atlantic, Viking ships of the ninth to eleventh centuries were a halfway step towards safe navigation. Built of overlapping planks nailed to a heavy rib and keel frame, and rendered waterproof by careful caulking, they were propelled either by oars or, when the wind was favorable, by a square sail. They dodged storms by going ashore or taking refuge in harbors along the Atlantic and Mediterranean coastlines of Europe and rowed up and down the rivers of Russia and western Europe as well. Sometimes they went raiding and destroying, sometimes they traded or set themselves up as rulers, and sometimes they pioneered

settlements of almost uninhabited landscape as in Iceland, Greenland, and, for a short while, even in Newfoundland. Viking boats were strongly built to cut through big waves, but since they needed large crews for rowing against the wind, they had limited cargo capacity and their open hulls allowed seawater to splash over the sides, soaking crew and cargo alike.

Really satisfactory all-weather ships needed closed decks, and ways to steer and sail upwind and against the tide if necessary. Such ships were eventually constructed in China and in Atlantic Europe, using quite different designs. Chinese ships were flat-bottomed vessels with hulls divided into separate water-tight compartments. Instead of keels, they had center boards that could be raised and lowered through a slit in the bottom, and were steered by stern-post rudders and by using multiple masts and sails. By the fourteenth century, the largest Chinese seagoing vessels were huge, expensive and efficient. Admiral Zheng He, for example, led a series of voyages to the Indian Ocean between 1405 and 1433, the first of which comprised sixty-two ships and carried no fewer than 27,800 men.

By that same date, sea-going European ships improved on Viking designs by being decked over, with double planked hulls nailed, inside and out, to a rib and keel skeleton as before. They dispensed with rowing by using multiple masts and sails, some triangular (originating probably in the Indian ocean) for tacking into the wind, some square for sailing before it. Such a combination of masts and sails, together with stern-post rudders (probably coming from China), made it possible to come and go almost at will despite the variable winds and strong tides that beset Europe's Atlantic coastlines. Indeed once sailors were capable of traversing those stormy seas, other oceans of the Earth, except the frozen Arctic, were comparatively easy since the reversible monsoons of Asia were matched by trade winds north and south of the equator that blow year round from a single but opposite direction.

Deciphering the pattern of ocean winds and currents was a matter of trial and error over generations,

Robert Fulton's first steamboat on the Hudson River, 1807.

as ships became capable of longer and longer voyages. Arab, Indian, Polynesian, Malay, Chinese, Japanese, European and other seamen all did so within their different, and sometimes overlapping ranges of operation. By 1492 such knowledge had accumulated among seamen so that Columbus, for example, knew exactly how to go south to the Azores, then sail west before the northeast trade winds and return by sailing north to the zone of prevailing westerlies beyond Cape Hatteras. That was why his voyage was so swiftly and regularly repeated, and why European seamen so suddenly began to traverse all the world's oceans within a mere thirty years after 1492.

Methods for measuring latitude north and south by sighting the sun or north star allowed ships to steer accurately towards a known coastline, and increasingly accurate local maps and charts made getting into and out of distant ports much safer. Magnetic compasses, coming from China initially, also allowed ships to maintain a steady direction under clouded skies where sun and stars could not be seen. But until the eighteenth century sailors could not measure east-west longitude. Finding small islands and exact time of arrival on familiar coasts across ocean distances therefore remained hit and miss until marine chronometers, able to keep time for weeks and months on end, made longitude at sea accurately measurable after 1762.

Nonetheless, European capabilities of ocean voyaging transformed human affairs rather quickly long before finding small islands became easy to do. The Chinese government had withdrawn from overseas

ventures after 1433 and disbanded its sea-going fleet so as to concentrate its resources instead on guarding China's land frontier against the Mongols. This left European seamen without serious competition on a global scale, since light-built shipping of the southern seas could not endure northern storms. The stout construction of North Atlantic ships also withstood the recoil of newly invented heavy cannon, and this gave European ships another advantage over more lightly built vessels. Cannon-carrying European ships made older ramming and boarding tactics of naval warfare suddenly obsolete since they could sink approaching enemies at a distance, and could even threaten local rulers ashore with punishing bombardment. Wherever such vessels appeared therefore local rulers had to accommodate them, allowing Europeans to come ashore for trade and sometimes paying them tribute.

Overall effects were especially catastrophic in the Americas and among other previously isolated populations. That was largely because unfamiliar lethal diseases brought by European seamen wreaked havoc on such populations, totally lacking, as they were, in acquired resistances to all the newly arrived infections. Drastic depopulation ensued, allowing newcomers from Europe, together with large numbers of slaves imported from Africa to transform the culture and character of American populations. Similar destruction and replacement took place in Australia, New Zealand and Oceania some centuries later.

The peoples of Eurasia and most of Africa were already disease-experienced, thanks to long-standing transport connections overland and by sea. Nonetheless, Eurasia and Africa were profoundly affected too by the onset of global seafaring. To put it in a nutshell: as coastal contacts became more and more significant for trade, for war and for exchanges of skill and ideas, the Eurasian continent was in effect turned inside out. Previously, China, India and the Muslim heartlands of western Asia had to concentrate attention on their land frontiers. Cavalry tactics, dating back to about 750 BCE, gave steppe nomads superior mobility with the result that adjacent farming populations suffered frequent raids and occasional

A bus station in central São Paulo, Brazil (pop. 20 million). An improved bus system is underway in the region to relieve a burdened public transportation infrastructure.

conquests across the next two millennia. Defending, negotiating, and competing against nomad states and armies was correspondingly critical for farmers of the Eurasian fringe lands. The Chinese government's decision to withdraw from the Indian Ocean in 1433 demonstrated that concern, only to open China to harassment from the sea when Portuguese ships showed up along the South China coast in 1513 and swiftly elbowed their way ashore at Macao by the 1540s.

India, Java and other Southeast Asian lands also allowed Europeans to set up fortified trading forts; and French, Dutch and English trading companies soon transformed themselves into local rulers. Ensuing armed struggles made the Dutch supreme in Indonesia and the English in India by 1763. Penetration of the Muslim heartlands was slower but after Napoleón's invasion of Egypt in 1798–1799, the Ottoman Empire and other Muslim states found it impossible to keep Europeans from demanding and getting trade and other privileges. East Asians held out until first the Chinese (1839) and then the Japanese (1854) saw their best efforts to keep Europeans at arm's length crumble under the threat of naval guns. Thereafter, efforts to transform old ways and somehow catch up with European power by appropriating at least some European skills

and ideas prevailed throughout the non-European world.

By that time, however, European intruders had acquired new advantages by using newly invented steamships and railroads to transcend older limits. Steam engines, fired by burning coal in the nineteenth century, and oil-burning internal combustion motors in the twentieth century provided far greater energy for transport, carrying greater loads much faster and far more predictably.

For ocean distances, practicable steamships dated from 1819 when a steam-assisted sailing ship first crossed the Atlantic. Rapid development ensued, featuring a sudden increase in size after 1858 (when iron construction replaced wooden hulls), and a subsequent race to speed up Atlantic crossings that reduced them to less than a week by the 1930s.

For river transport, shallow-draft flat-bottomed steamboats with paddle wheels amidships flourished mightily for half a century after 1807, when Robert Fulton made his successful run up the Hudson River. Steamboats, however, suffered eclipse in the United States after the 1860s, since railroads proved faster and more convenient. Nevertheless, they remained of critical importance on African rivers and in parts of Asia where railroads were not built until roads and trucks supplanted them after about 1930.

The Advent of Rail Travel

For overland transport, steam powered railroads followed close behind oceanic steamships. The first commercial steam railroad, 25 miles long, opened in England in 1825; but building longer railroads was costly and took time. Railroads therefore began to come into their own only in the 1860s. The first transcontinental railway opened in 1869 when the Union Pacific Railroad in the United States was completed. Thereafter European investors financed railroad building wherever strategic or commercial advantages suggested. The opening of the Trans-Siberian Railroad in 1903, connecting St. Petersburg on the Baltic with Vladivostok on the Pacific, was the longest railroad ever built and still helps to hold the Russian state together.

In western Europe itself, railroads gave easy access to inland coalfields, accelerating industrial development enormously. Railroads also played a prominent part in European wars as early as 1859, climaxing during World War I (1914–1918) when railroad schedules for mobilization locked initial war plans into place, and subsequently supplied all the war fronts for years on end.

The impact of railroads was especially great in large countries like the United States, Russia, Canada, India, and Argentina, binding them together internally more closely than before while also entangling them in worldwide markets. China as always remained different, for old-fashioned barge transport on internal waterways continued to function slowly but cheaply; and for more than a century political instability inhibited large-scale railroad construction.

For the world as a whole, steam ships and railroads together created a far faster and more capacious transport system than before. Millions of persons emigrated from crowded lands in the Old World to settle in the Americas, Australia, New Zealand, and South Africa. Vast quantities of grain and other foods, together with minerals and other raw materials, and innumerable manufactured goods began to circulate throughout the world. Simultaneously, European intruders took advantage of steamboats

and railroads to penetrate China and Africa as never before. Japan, however, built its own railroads and steam ships. Everywhere else the new modes of transport were owned or managed by Europeans or persons of European descent until well into the twentieth century.

Until 1945 or so, Europeans retained this privileged position and, by making some accommodation to the United States after 1865, managed world affairs pretty much to suit themselves. Near monopoly of mechanical transport and communication sustained this lop-sided arrangement for a while, but it remained inherently unstable. One such instability arose from rivalries among the chief European states, climaxing in two world wars, 1914–1918 and 1939–1945. Just as important was the way the propagation of the new transport (and communication) nets among Asian, African, and American populations allowed local peoples to mobilize their discontents and prepare to assert control over their own societies again. As a result, soon after World War II European colonial empires disintegrated everywhere.

New Modes of Transport in the Twentieth Century

More decentralized and flexible forms of overland transport powered by internal combustion motors sustained this political transformation. Cars and trucks first became important for the transport of goods and persons during World War I. Trucks commonly carried loads door to door, diminishing transfer costs. In addition, individuals and small companies could compete with larger fleets of trucks on more or less even terms. Roads still had to be built and maintained by public authorities and remained costly. But roads were considerably cheaper to build than railroads. Hence for hauls of less than three or four hundred miles, the convenience and flexibility of trucking was almost as superior to railroad transport as railroads had been to river steamboats eighty years before.

Almost simultaneously, airplanes began to affect transport. Airplanes took off with the Wright brothers' flights in 1903, but World War II was what

China's most popular means of transport. With imported cars clogging the roads, and narrow *hutong* alleyways to traverse, the Chinese depend on their bicycles.

made them important for transport, a generation after cars and trucks had come of age during World War I. Transcontinental flights were pioneered in the 1930s, but Allied armed forces first made large-scale air transport global between 1941 and 1945. Planes became faster and larger in the following decades and air transport expanded accordingly. By the 1950s, variously subsidized national airlines combined to make tourist and business travel by air normal. Air delivery of mail and important packages displaced older means of transport for long distances; but airplanes seldom carried heavy objects or bulk commodities. Their high speed came at a cost that made air transport a semi-luxury.

All the same, in Arctic lands and some other barren and remote regions, light airplanes became the

only way to come and go, while long-distance flights, following great circle routes, crisscrossed the globe, weaving a new pattern that made passage across high northern latitudes important as never before. Another side effect of flight was the establishment of uniform weather reporting, and use of English for air traffic control at airports everywhere—including even the Soviet Union during the Cold War.

Rockets were yet another form of transport emerging from World War II, but their loads remained far more restricted. Explosive warheads were the most threatening, but have never been used in practice. The most significant rocket flights launched various satellites and sensors into orbit around the Earth, or, in other cases, escaped Earth's gravity to explore the solar system and fringes of the universe beyond. Such sensors have expanded information about the Earth, moon, planets and stars enormously since 1957 when the Russians first launched *Sputnik* into orbit. Americans countered with the feat of sending men to the moon in 1969 and returning them safely. But the future of space travel remains uncertain. Being extremely costly, it will not likely affect everyday life in the way older changes in methods of transport have done throughout the past. But disaster from nuclear warheads delivered by rockets still remains a threat to the future of humankind.

Human beings have invented more and more powerful ways of moving themselves and other things across the face of the Earth and, more recently, through the air and into outer space. Successive systems of transport defined the range and intensity of contact local populations had with outsiders; and those contacts in turn regulated the frequency with which important new things, skills, and ideas caused people to abandon familiar ways and try something new. Accordingly, as transport and accompanying communication intensified, the pace of social change accelerated, distressing most of the people affected.

This is the awkward state of human society today. But as always the future remains unknowable. Nonetheless, transport will continue to affect how

people live, altering everyday experience by bringing novelties from afar for us to accept, reject, or modify just as our predecessors have always had to do.

Travel Guides

For centuries travelers around the world have set out on journeys for a number of reasons—the love of adventure, spiritual pilgrimage, or to seek fame and fortune. Travelers recorded accounts of what they saw, heard, and experienced for both current and future wayfarers to consult. Thus, travel guides are valuable sources for studying global history.

The travel and tourism industries, analyzed globally, generate billions of dollars annually. The national economies of some countries rely heavily on tourists who visit for either work or recreation. Travel also affects other industries. The financial stability of the transportation system, comprised largely of airplanes, ships, and rail and road networks, is dependent upon travelers' willingness to journey beyond the confines of their home. The hospitality and restaurant industries profit from travelers' business. Modern travel guides, such as *Fodor's*, *Lonely Planet*, *Rough Guide*, and *Routard*, are lucrative for their publishers. New editions of travel books appear annually, focusing on tourist destinations around the globe. These new editions are read by novice and veteran travelers alike, eager to see the newest recommendations of restaurants, lodgings, and sights.

Yet, travel guides have a much longer history. For centuries travelers across the globe have embarked on journeys for a variety of motives. Such motives could include economic gain, spiritual solace, or merely the love of adventure. Travelers have recorded their sights and thoughts for both current and future wayfarers to consult. Thus, travel guides function as extremely valuable sources for studying global history.

Greek and Roman Travelers

Because the Roman Empire was physically extensive—about 4,800 kilometers from east to west—a system of well-designed and engineered roads and bridges was necessary for its successful administration. The Latin adage *omnes viae Romam ducunt* (all roads lead to Rome) attested to the safe, well-maintained network of roads that could permit a traveler to journey from the farthest regions of the empire to its heart.

Additionally, Rome was a cosmopolitan empire, with more than 50 million inhabitants, all of whom spoke various languages, worshipped many local and imperial deities, and engaged in a plurality of customs. The eastern provinces of the empire, where commerce and civilization flourished long before the Romans appeared, had a historic cultural and cosmopolitan legacy, ensuring its popularity as a travel destination during antiquity.

Greek epic poetry, such as Homer's *The Iliad* and *The Odyssey*, circa 800 BCE, conveyed the sense of excitement, but also danger, of travel. One of the earliest travel narratives is that of the Greek historian Herodotus. In his *Histories*, written around 440 BCE, Herodotus recorded his personal observations of his extensive travels in the Mediterranean basin, visiting places such as Egypt, the Black Sea, Scythia, Mesopotamia, Babylon, Cyrene, North Africa, and Anatolia (in modern Turkey). Ancient Greek writers who probably traveled to India included Ctesias (c. 398 BCE) and Megasthenes (c. 303 BCE).

Natural History (c. 77 CE) by the Roman writer Pliny was another travel account that influenced later

As the traveler who has once been from home is wiser than he who has never left his own doorstep, so a knowledge of one other culture should sharpen our ability to scrutinize more steadily, to appreciate more lovingly, our own. • Margaret Mead (1901–1978)

Europeans' perspectives concerning the world outside of Europe. Like Herodotus, Pliny recorded his firsthand observations of his travels in the world around him. But some parts of his work, such as his discussion on the “monstrous” races of the world outside of Europe, clearly had a basis in myth, bias, and a fear of the unknown.

East / West Connections

Although Pliny's account is not generally favorable toward non-Romans, his depiction of monstrous races nonetheless sparked Europeans' imaginations. Moreover, the sight of luxury goods—including Chinese silk, southeast Asian spices, Indian cotton textiles and pearls, and central Asian horses and jade, which traversed the central Asian Silk Roads—whetted Europeans' appetite for “exotic” items. The Romans, in turn, offered Asian markets various products, including glassware, jewelry, art, bronze, olive oil, wine, and gold and silver bullion.

Merchants and diplomats who traversed the branches of the Silk Roads recorded their observations. For instance, the detailed travel accounts of the diplomatic mission of Zhang Qian (d. 113 BCE), recorded in Sima Qian's *Shiji* (Records of the Grand Historian, c. 100 BCE), provide extensive information about the peoples and lands of central Asia, Persia (modern Iran), and northern India. This connection between East and West was not permanent, however. The collapse of the Han dynasty (206 BCE–220 CE), compounded with near-contemporary third-century crises of the Roman Empire, disrupted trade along the Silk Roads.

An Early Medieval Pilgrimage Travel Guide—The *Codex*

Religion also motivated travelers. The pilgrimage was a form of travel in which a person, as a form of devotion or penance, walked from his or her home to a shrine. Located at the shrine were relics—bits of clothes and/or body parts of saints, to whom the travelers could pray for intercession.

One of the most popular pilgrimage routes for medieval Christians led to the shrine of Santiago de Compostela, located in Galicia, the northwestern corner of the Iberian Peninsula. Surpassed in importance only by Jerusalem and Rome, the cathedral at the end of the 800-kilometer route housed the relics of Saint James, one of the twelve apostles. Pilgrims from all parts of Europe followed the route through the mountainous northern coast of Spain to Galicia. Because of the popularity of the route, the cleric Aimeric Picaud, between 1130 and 1140 CE, edited the *Liber Sancti Jacobi* (The Book of Saint James), also called the “*Codex Calixtinus*.” The fifth book of the *Codex* was essentially a pilgrim's guide and described to pilgrims the terrain and conditions of the land, pointed out major sights along the route, and warned them of hazards that could waylay the unfortunate pilgrim.

Medieval Travelers—Marco Polo and Ibn Battuta

Possibly the most famous travel narrative and guide of the Middle Ages was by the Venetian merchant and diplomat Marco Polo (1254–1324 CE). *The Travels of Marco Polo*, also known as the *Description of the World*, was a wildly popular account of his travels and travails. It was massive in its geographic focus, detailing the lands from Japan to Zanzibar. As a youth, Marco Polo had traveled from Venice with his father and uncle, who had made a prior journey to China, to the East to establish a new outlet for European exports. He spent about twenty years living and traveling in the East in the service of the founder of the Mongol dynasty, Khubilai Khan (d. 1294 CE), and traveled to China, Burma (modern Myanmar), India, central Asia, and Byzantium (modern Istanbul, Turkey). He undertook a three-year maritime return journey, returning to Venice in 1295 CE. Captured at the Battle of Curzola on 6 September 1298, Marco Polo was imprisoned in Genoa and there met Rustichello da Pisa, an author of romances, who eventually published Marco Polo's account. But Rustichello certainly fabricated parts of the text to create a gripping narrative; the presence of bandits, pirates, and wild animals points to the

hazards of travel. The luxury and common goods that pepper Polo's story point to the commercial nature, and rewards, of an enterprising journey.

A medieval narrative that can compare with Marco Polo's is the fourteenth-century *rihla* (travel narrative) of the Moroccan Abu 'Abdullah ibn Battuta (d. 1369 CE), *A Gift of the Observers Concerning the Curiosities of the Cities and Marvels Encountered in Travels*. From 1325 to 1349, Ibn Battuta traveled extensively and related his observations and experiences during his hajj (religious pilgrimage to Mecca in Saudi Arabia) and his subsequent travels within the dar al-Islam (Islamic world), from North Africa and the Arabian Peninsula to Delhi, Ceylon (modern Sri Lanka), Bengal, China, and Mali.

Early Modern Travelers

Travel writings did not cease with the "closing of the ecumene"—the arrival of Europeans in the Americas with the first trans-Atlantic voyages of the Genoese sailor Christopher Columbus (1492–1493). Columbus owned a highly glossed account of Marco Polo's travels, attesting to the influence that travel guides had upon exploration. From the fifteenth through the seventeenth century Europeans traversed the globe in increasing numbers, and with the development of the printing press, the volume of travel narratives exploded. The Englishman Richard Hakluyt (d. 1616), in addition to writing travel narratives, published accounts of travel and exploration to spur his countrymen to undertake additional journeys. In 1686 the French Huguenot Jean Chardin (1643–1713) published the first part of his narrative about his travel through the Safavid Persian Empire, *The Travels of Sir John into Persia and the East Indies*. In it he gave information about contemporary Persian customs, education, and mannerisms to an increasingly literate society.

The Eighteenth-Century "Grand Tour"

During the eighteenth century, to be young, wealthy, and of noble descent meant that one could embark

upon the "Grand Tour," an excursion that could last from months to years and during which one could learn about European politics, art, and culture. The tour became central in contributing to the education of young British aristocratic men. They especially favored Italian destinations, including Turin, Venice, Florence, and above all Rome because of its grandeur. The letters of William Beckford (1760–1844), published in 1783, comprise one of the most famous travelogues of the Grand Tour, romantically entitled *Dreams, Waking Thoughts and Incidents, in a Series of Letters, from Various Parts of Europe*. The latter half of the eighteenth century brought an increase in political stability for Europe as well as rapid technological advancement spurred by the Industrial Revolution, which made cheaper, safer travel easier. Nineteenth-century English travel literature, written by explorers, missionaries, and diplomats, was extremely popular among the literate classes, served British imperialist interests, and depicted the often-tragic encounters between indigenous and European peoples.

Perspective

The continuing historical analysis of the immense body of rich and unique primary sources that make up travel literature will provide answers to questions concerning history, anthropology, and ethnography (study of culture). Further studies of travelers' guides, many of which still await scholarly analysis, undoubtedly will offer increasingly nuanced understandings of the economic, political, social, and cultural interactions engendered by travel.

Treaty of Versailles

Negotiations at the Paris Peace Conference established the terms of post-World War I peace between the Allies and Germany, and culminated in the Treaty of Versailles signed on 28 June 1919. The process and the terms were highly controversial, and ultimately the League of Nations it established was ineffectual. The ensuing dissatisfaction, malaise, and revolt would eventually lead to World War II.

The Treaty of Versailles was the first and most important of the treaties that ended World War I. Signed at the Palace of Versailles outside Paris on 28 June 1919, the treaty was the product of the Paris Peace Conference. In essence the treaty established the terms of peace between the victorious “Allied and Associated Powers” (principally the United States, the British Empire, France, Italy, and Japan) and Germany.

The Paris Peace Conference itself opened on 18 January 1919. The key participants included U.S. president Woodrow Wilson, French prime minister Georges Clemenceau, British prime minister David Lloyd George, and Italian prime minister Vittorio Orlando. The victorious powers required almost four months to agree on the terms of peace. In addition, the conference determined the shape of the new League of Nations and the International Labor Organization. Only in late April, when a draft treaty was at last agreed upon, were the Germans invited to Versailles. Count Ulrich von Brockdorff-Rantzau, a career diplomat, led the German peace delegation representing the new Weimar Republic.

Quite apart from the terms of the treaty, the process of peace making at Versailles was intensely

controversial. Participants gave little thought to the consolidation of Germany’s new democracy. The treaty was handed to the Germans, as a virtual fait accompli, at a ceremony at the Trianon Palace Hotel on 7 May 1919. Clemenceau warned that no round-table negotiations would be contemplated. On 29 May the German delegation submitted a formidable list of counterproposals, complaining that the terms were scarcely reconcilable with either the spirit or the letter of President Wilson’s liberal speeches of 1918. In response, however, the victorious powers offered few amendments. On 16 June Clemenceau demanded a German signature to the treaty within five days (later extended to seven days) and threatened to resume the war if Germany failed to sign. Therefore, the German government was under immense pressure. In particular, the continuation of the economic blockade throughout the armistice period worsened a serious food crisis inside Germany that weakened the government’s bargaining position. The socialist-led government of Philipp Scheidemann resigned rather than sign the treaty as it stood. But a new socialist-led coalition government, under Otto Bauer, bowed to the inevitable and sent emissaries to sign.

Territorial Terms

The principal territorial terms of the treaty imposed significant transfers of territory from the former German Empire to its neighbors. Alsace-Lorraine was returned to France (restoring the border of 1815–1870). In the East a territory of 43,000 square kilometers, forming the greater part of the provinces of Posen and West Prussia, was ceded to Poland. This

territory, often referred to as the “Polish Corridor,” separated East Prussia from the rest of Germany. The city of Danzig, at the north of the Polish Corridor, was made a “free city” under the administration of the League of Nations. Memel in East Prussia was also ceded and eventually incorporated into Lithuania. In the west small border territories around Eupen and Malmédy were ceded to Belgium. Postwar plebiscites (votes) were also imposed in order to settle new territorial boundaries in a number of disputed zones: in Schleswig (resulting in the transfer of one zone in north Schleswig to neutral Denmark in 1922), in East Prussia (resulting in Germany’s retention of territory around Allenstein and Marienwerder in 1920), and in Upper Silesia (resulting in the division of the province between Germany and Poland in 1922). In addition to these territorial changes, the Rhineland, including three key bridgeheads beyond the Rhine River, was subjected to military occupation for fifteen years by Allied and Associated troops. The Saar River basin was transferred to the administration of the League of Nations for fifteen years (to be followed by a plebiscite), during which time the coal mines of the area were to be placed under French ownership. The greatest transfers of territory, however, took place in colonial possessions. Germany was deprived of its entire colonial empire. Under a complex system of League of Nations mandates, the former German colonies, containing almost 13 million people, passed to the administration of the victorious powers.

The military terms of the treaty achieved Germany’s effective disarmament. The army was reduced, by stages, to a maximum of 100,000 men, on the basis of voluntary enlistment. The Rhineland was demilitarized with respect to German arms and fortifications. The navy was reduced to a tiny fraction of its former size, and Germany was not permitted to possess any battleships of the dreadnought class, nor any submarines. Germany was not permitted to retain any air force. The German government offered little resistance to these provisions but insisted that disarmament should be applied to all nations.

Reparations

Germany especially resented the economic and financial provisions of the treaty. This resentment arose from the controversy surrounding reparations. During the war President Wilson, although rejecting the prospect of any punitive indemnity, had conceded the justice of reparations. Other victorious powers, and Britain in particular, hoped to achieve an indemnity within an expanded claim for reparations. At Paris, much to the chagrin of his own advisers, Wilson surrendered to pressure from Britain and France in favor of significant economic penalties against Germany. In an effort to appease popular expectations in Britain and France for a vast indemnity, negotiators drafted the notorious Article 231. This article asserted Germany’s responsibility for “causing all the damage” that the victorious powers had suffered “as a consequence of the war imposed upon them by the aggression of Germany and her Allies” (Sharp 1991, 87). Article 231 was soon interpreted inside Germany as an assertion of Germany’s sole responsibility or “guilt” for causing the war. It was alleged by German critics that this assertion of exclusive German war guilt underpinned all the economic clauses of the treaty. A huge indemnity was clearly in excess of the “compensation . . . for all damage done to the civilian population” (Schwabe 1985, 85), which Germany had accepted in diplomatic exchanges preceding the armistice (the Lansing Note of 5 November 1918). In the treaty Germany was obliged to accept an unspecified total of reparations. This total was likely to be massive because it had to cover a much-expanded list of legitimate damages drawn up by the Allies, including pensions to Allied servicemen. The treaty named no final total to be paid by Germany, but rather the Reparations Commission was established and charged with reporting a final total by May 1921.

The treaty’s consequences were of tremendous significance. In Germany the liberals and democratic socialists were smeared as “November Criminals” who had betrayed Germany by launching a revolution to

achieve democracy and peace on 9 November 1918. The revolution, it was alleged, had disabled Germany and ensured her defeat. In the eyes of rigid nationalists, democracy in Germany symbolized national humiliation. The victorious powers also did much soul searching. Critics argued that the victorious powers had undermined their own moral authority. The most influential criticism was by the British economist John Maynard Keynes. He had left the Paris Peace Conference in protest in June 1919 and published his passionate denunciation of the treaty, *The Economic Consequences of the Peace*, in December. In the United States, Wilson's failure to carry his own vision of a peace of reconciliation marked the treaty as a defeat for all those people promoting liberal internationalism. Disappointed liberals disavowed Wilson and the treaty. This disavowal contributed to Wilson's eventual failure to persuade the U.S. Senate to support either the treaty or U.S. entry into the League of Nations, despite a longer-running political campaign in 1919–1920. The U.S. decision not to enter the new league did much to debilitate the league during the 1920s and 1930s.

Trees

Trees are vastly older than the human species, and the study of trees is itself a vast subject. With its focus on human/tree interaction through the ages, this article considers trees as objects of human veneration, as sources of food or obstacles to agriculture, and as wildlife whose “behavior” is affected by human actions.

Trees evolved some 360 million years ago, long before the humans whose cultures venerated them throughout history for spiritual or aesthetic reasons. Human interactions, however, from the earliest hunter-gatherers in the forests of the Paleolithic, have posed threats to forests and woodlands. Today the most serious involves the “mixing up” of diseases and pests from one part of the world to another.

Trees before Humans

Trees are wildlife. They have existed for very much longer than people. Over 360 million years ago they evolved their own diverse agendas in life before they ever knew human contact. There are now tens of thousands of species of trees, each doing its own thing. All trees form partnerships with fungi, and many with ants and pollinating insects and birds. Different species grow from the tropics to the fringes of the arctic. Some grow in forests, some in savannas (grassland with scattered trees). Some are eaten by animals, some are distasteful or poisonous; animals evolved in turn to depend on trees in a multitude of ways, from the super-elephants that could break down and devour a big tree to the primates (forerunners of humanity) and birds that live on tree fruits and seeds. Some trees will burn and sustain forest

fires (many trees depend on fire for their continued existence or propagation); others are incombustible. Some grow from seed, others from root sprouts.

In the last two million years, climatic changes of the ice ages, which rendered much of the world’s land area incapable of growing trees, disrupted this story of gradual change and adaptation. Trees found themselves having to make do with environments into which accidents of history thrust them.

Trees before Farmers

Next appear the hominids (other species of mankind) followed by the human species itself. In Africa, their land of origin, people probably dwelt in savannas, but over tens of thousands of years they came to inhabit both forests and the treeless landscapes of cold or dry climates. Humanity at this stage—small numbers of hunter-gatherers—would have interacted with trees in four ways:

1. Tree fruits and other products presumably formed part of the human diet; thus Mesolithic people took advantage of the nuts in the vast extent of hazel woodland in Britain.
2. People developed tools for felling small trees, which provided firewood and the material for wooden artifacts. (The name Stone Age is misleading because the stone tools that have survived were probably far less numerous than the wooden objects that have not been preserved.) As yet, the quantities involved would have been insignificant in comparison with the growth-rate of trees.
3. Wherever savanna or forest happened to be flammable, people used fire in land management,

manipulating the vegetation in favor of those animals and plants that they preferred.

4. Early humanity was probably responsible for exterminating the super-elephants and other living bulldozers, which survive in an attenuated form in Africa. In turn this would favor the growth of trees.

Arguably, the last two examples represent the greatest effects that the human species has had (until now) on the world's vegetation. Whether Paleolithic and Mesolithic people interacted with trees in cultural and spiritual ways, and whether this made any difference to the trees themselves, it is impossible to say.

Trees before Metals

Further interactions came within the last 10,000 years. After the last ice age, trees returned to northern countries like Britain; traditionally they are thought to have generated a continuous "primeval forest," which in practice may have been more savanna-like, with areas of grassland. Then people acquired the Neolithic arts of farming, keeping livestock and growing crops, building permanent houses, and indulging

in pottery, temples, graveyards, and all the trappings of settled civilization. These were invented separately in various parts of the world and spread slowly almost throughout the globe, except in Australia.

In temperate climates trees are the farmer's enemy, because arable crops will not grow in shade. Common domestic animals require open grassland. They live in forests only in small numbers: they eat the low vegetation and when that is gone they starve. Hence farming began in savanna or grassland, since cultivation of forested lands required a great investment of effort in digging up trees and making fields. This is documented with European settlement in America; presumably it happened also in northern Europe in Neolithic times, but without the metal tools and labor-saving devices available to settlers in historic times.

In the tropics, matters would have been somewhat different because some tropical crops grow in shade and some of the trees themselves have edible fruit. So forests were not necessarily destroyed but sometimes converted to orchards and cultural savanna.

At this stage if not earlier, people made the momentous discovery that some trees sprout from the stump or roots when cut down, and the resulting

Jean-Pierre Houël, *Castagno dei cento cavalli* [The Chestnut Tree of One Hundred Horses] (1782). Gouache. Located 8 kilometers from Mt. Etna's crater, this is the oldest known chestnut tree in the world. According to legend it sheltered a queen of Aragon and her company of a hundred knights when caught in a thunderstorm during a trip to the mountain.

If you reveal your secrets to the wind, you should not blame the wind for revealing them to the trees. • **Kahlil Gibran (1883–1931)**

poles are more useful than the original tree-trunk. Thus woodland management originated, of which the first certain evidence comes from the Neolithic of the Somerset Levels in England, some five thousand years ago. People could (with difficulty) fell forest giants, but big trees of most species have only one use before the invention of power tools—making dugout boats. The human population, although increased from hunter-gatherer times, was still too few to have more than a local effect merely by cutting down trees.

Thus began the characteristic ways in which settled people influence forests:

1. Digging up trees in order to use the land for farming.
2. Cutting down trees in order to use the timber or wood, either for carpentry or as firewood (including fuel for making pottery).
3. Managing the remaining woodland in order to produce a permanent supply of trees small enough for one or two men to handle.
4. Exterminating or reducing many of the wild herbivorous animals.
5. Replacing wild beasts with domestic livestock, often in large enough numbers to hold back the regrowth of felled trees.
6. Moving tree species around the world, for example the cultivated apple, brought to Britain by the Romans from its native Kazakhstan.

From small beginnings in the Neolithic these spread around the globe. It has been claimed that even in prehistory the reduction in forests was sufficient to have a significant effect on the carbon dioxide content of the atmosphere. However, the land area involved seems too small to account for the known carbon dioxide anomaly—unless, perchance, the equation needs to include the efforts of Australian Aborigines and American indigenous populations in preventing forests from overrunning the vast areas of savanna in those continents.

A less familiar use of trees is pollarding or shredding, that is, cropping the branches to provide leaves on which to feed livestock. This began in the Neolithic,

as cattle and sheep were introduced into forested regions that lacked grassland. It still continues in parts of the world where the growing season for grass is brief. Trees so treated are often very long-lived and grow into characteristic shapes.

Trees before Intercontinental Travel

In later prehistory uses of trees multiplied, especially in those cultures that invented metals. Bronze and iron made it easier to cut down trees and also greatly increased the need for fuel to smelt and work metals. The Romans had an abundance of fuel-using activities—baths, brickmaking, glassmaking, as well as domestic heating and making throwaway pots. Increasing population as well as developing technology multiplied the demands on the woods. Only locally, however, was mere human labor yet sufficient to cut down trees faster than they could grow again. It was possible to transport and work great trees for exceptional purposes, such as the roof timbers of Solomon's Temple in Jerusalem, but this was a rare achievement: in most cultures trees small enough to handle were the stuff of everyday uses.

By late prehistory humanity had come to affect virtually all the world's mainland forests and savannas, at least by interfering with the relation between trees and herbivorous animals and (where applicable) by altering the frequency of fire. Islands such as those of the Mediterranean, which already had native mammals, were probably not much affected by human settlement; but particularly devastating was the later effect of introducing goats and pigs to oceanic islands like St. Helena, where the vegetation was not adapted to any sort of land animal. The last large areas without human contact were Madagascar and New Zealand, reached by humanity around 2,000 and 800 years ago. The world's very last "virgin forests," unaffected by humanity, were probably on some remote island in the eighteenth century.

Agriculture gradually spread from its homeland in the sparsely tree'd regions of southwestern Asia into the much more wooded and less congenial regions of Europe. Even now, little is known of how, still less

why, forests were converted into farmland. Although arable farming in Italy was well developed from the Neolithic onward, even in imperial Roman times the great city of Rome transported most of its food supply from North Africa, leaving Italy to supply most of its timber and fuel.

England followed an apparently unusual pattern with its high density of population. By the Iron Age (the last few centuries BCE) most of the wildwood had given way to farmland or moorland, and the pattern of the modern countryside was already developing. Domesday Book, a survey of 13,418 English settlements commissioned by William the Conqueror in 1085), gives uniquely detailed statistics of a landscape in which only 15 percent of the area was woodland, less than France has now. This was reduced still further, to only about 6 percent by 1349, when the Black Death put an end to increasing population.

Woodland conservation probably originated from the need to maintain a continuous supply of smallish trees, but gained a further impetus as woods acquired scarcity value (i.e., the less of a commodity in existence, the more it is worth). In England many woods mentioned in medieval documents are still there today; they are recognizable by their distinctive names and shapes, by banks and ditches protecting

the boundaries, the massive bases of coppice stools (trees that have been felled and have grown again and again), and special plants that do not spread into recent woodland.

Trees also grew in hedges and other non-woodland situations to supply timber and underwood. Orchard culture developed from Roman times onward in Europe and independently in other continents.

International trade in timber—both precious timbers like Cretan cypress and ordinary timber—became significant in the Middle Ages. England, the Netherlands, and Spain drew increasing quantities of pine and oak from the Baltic: not merely because they had insufficient woodland of their own, but because the exporting countries had developed equipment and skills for processing trees.

Destruction of forests to create farmland and pasture was not a one-way process. Trees grow very easily provided they are left alone. Whenever land was abandoned through pestilence or slave-trading or because people discovered an easier way to make a living, woods returned or savanna turned into forest. Thus in England many of the great wooded areas of the Middle Ages contain remains of farms, settlements, and monuments of prehistory or Roman times.

Ramses and the Tree of Life, a nineteenth-century illustration, depicts an Egyptian mural painted circa 1330 BCE. New York Public Library.

Cultural and Spiritual Qualities of Trees

Ethnographers have described a vast diversity of relations between people and trees other than the physically utilitarian, ranging from the overtly spiritual (a tree as the home of a god) to the purely aesthetic (a tree providing a “splash of color” in a formal garden).

Veneration and love of trees are characteristic of a very wide range of separate human cultures, but largely lack a time-dimension unless there are written records. The exact part played by the trees is often ill defined, since travelers who were half-informed about (or hostile to) another culture were often the ones to record information about it. Whether trees played any part in the ancient designs of Stonehenge or Angkor Wat is difficult to say unless remains of the trees themselves survive. Archaeologists are seldom perceptive in detecting and recording surviving trees among the ruins of ancient sites.

Individual trees have been widely venerated as the home of minor gods, as with the sacred trees in the ancient city of Rome, or the innumerable sacred trees (of many species) in the Shinto religion of ancient and modern Japan. Conversely, all the trees of a particular species, or big trees in general, may be venerated. Many religions have sacred groves surrounding temples and shrines, or in which rites and ceremonies are enacted. Particular species may play a part in celebrations, like laurel in the triumphs of ancient Rome, holly at Christmas, and palms (or some northern substitute for palms) on the Christian Palm Sunday.

Monotheistic religions celebrate specific sacred trees, at least unofficially. Jews, Muslims, and Christians venerated “Abraham’s Oak,” at Hebron in Palestine. England has its ancient churchyard yews, some dating from the early centuries of Christianity. In Wales, ancient yews are associated with the saintly hermits of the first millennium CE.

Trees in parks and gardens—other than fruit trees—are a feature of many cultures. The sacred groves of the ancient Greeks, like those of Buddhist temples and Shinto shrines in modern Japan, could range from natural woodland to formal gardens. The

ancient Romans set up secular parks and planted trees in them, preserving as well the existing trees. How far this applies to other monumental cultures that have no written records is difficult to say.

Urban trees vary enormously. Most towns and cities of the Middle Ages were small and closely packed, seldom with room for many trees, apart from trees on sacred sites embedded in the city or on flood plains. With more diffuse fashions in town planning from the eighteenth century onward, urban trees became a normal feature, to the point that many European and American cities now have more trees than the surrounding countryside.

Appreciation of ancient and distinctive individual trees is widespread in human cultures, but is not universal. In England, ancient trees were preserved as giving an air of respectable antiquity to a new country-house park: this veneration ebbed in the mid-twentieth century but has since revived with renewed interest in “veteran trees.” Notable ancient trees occur in the Mediterranean, especially olives and chestnuts. In Japan, ancient trees are venerated as memorials to past emperors, are preserved even when dead, and are imitated in miniature in the craft of bonsai. Most ancient trees are monuments to cultural activities such as pollarding or orchard culture.

Trees also have medicinal and magical uses in many cultures, although not to a greater extent than other plants. Well-known examples are quinine bark as a treatment for malaria, or the British naturalist Gilbert White’s account of the “shrew-ash,” a tree used for treating the ailment of cattle supposedly caused by shrews running over them.

Trees in the Age of Machinery

The seventeenth to twentieth centuries saw further technological development. Many inventions had begun in a small way in the Middle Ages, but now were employed on a much larger scale and taken to woods in distant parts of the globe.

Discovery and colonization let loose European-style agriculture on other continents. Destruction of forest and savanna to make farmland, which in

Europe had taken thousands of years, was compressed into decades in America and Australia. Even well into the twentieth century much of this was still done by multitudes of axe men and oxen, followed by special “stump-jump” machinery for cultivation.

Woods increased in other countries, especially where the ground was too infertile or too steep for mechanized farming. In eastern North America in the nineteenth century and in the Mediterranean in the twentieth, huge areas have reverted to forest.

Shipbuilding had previously had a local influence on woodland. But as ships got bigger and more numerous, went to distant continents and spent long periods rotting in tropical waters, and as European navies indulged in arms races, timber shipbuilding increased until for a short period (1800–1860) it was a major influence on European woodland and even affected tropical forests.

In the nineteenth century international trade turned intercontinental as North American pines and tropical hardwoods were widely used in Europe. People developed technologies for felling and converting big trees. Sawmills, another medieval invention, became more widespread and bigger until (with the help of railways) a use was at last found for rain-forest giants. In what was presented as a triumph of technology, the giant trees of the Pacific coast of the United States, of southwestern Australia, and of the more accessible parts of the tropics were converted into railway sleepers, fence posts, and paving blocks.

Forestry plantations—or areas of trees for timber—were invented in medieval Germany and independently in Japan. From then on it became possible (in theory) to grow trees for specific uses—assuming that those uses would still exist by the time the trees had grown. There have been several attempts at planting trees on a huge scale in dry countries, in the belief that this would restrict the spread of deserts. In the nineteenth century plantations became the staple of modern forestry; German or French forestry ideals and practices were imposed on countries like India and later Britain, marginalizing local practices and skills. By the late twentieth century native forests were being destroyed and replaced by plantations,

in countries like Chile and Tasmania, on a scale that gives rise to great concern among conservationists. There is a risk that natural forests will become confined to steep slopes, nature reserves, and other areas beyond the reach of machinery.

Ancient management practices were neglected. In England competition from the increasing use of coal, transported by railways to rural areas, led to woods being abandoned as sources of fuel. Japan, like England, took to plundering other countries’ wildwood for timber supplies while neglecting its own woods.

Forests and savannas are threatened by the effects of humanity on mixing up all the world’s animals and plants. A famous example is the frivolous introduction of the grey squirrel from North America to Britain, where it has multiplied to an extent which threatens the very existence of some indigenous trees; it has also reduced the native red squirrel to near-extinction.

This applies to plants also. Why is it so easy to destroy tropical rainforest? Felling the marketable trees might not matter much: the redwood forests of Pacific America have grown again (although they have probably not recovered all the plant and animal life of the original forest). When trees are felled now, however, the site is often taken over by one of the giant “elephant-grasses” from another part of the tropics; these interfere directly with the regrowth of the trees, and also are very flammable, introducing fire to forests that previously did not have it and are not adapted to it.

Climate change has some effect. Tropical forest trees are growing faster than before, possibly in response to increased carbon dioxide in the air. Trees confined to mountaintops, as with some tropical cloud-forests and the “sky islands” of the southwestern United States, are threatened because they have nowhere to go in the face of warming climate. But the most significant effect of global warming is probably where trees have been introduced into places where they do not withstand increasingly hot summers, as with some beech and spruce plantations in England.

In the late twentieth century big game increased in many parts of the world to the point where plant and bird life, and even the existence of woods is

threatened. England now has more deer than for over a thousand years, and more species of deer than ever before: deer eating woodland have become the top conservation problem. The same happens in much of North America, partly because hunters demand artificially huge numbers of deer to shoot, and even in Japan.

Probably the greatest threat to the world's trees and woods is the effect of twentieth-century humanity in mixing up all the world's pests and diseases. In the state of Ohio, in less than a hundred years, chestnut, most elms, many oaks, flowering dogwood, and fir have been removed, each by its accidentally introduced European or Asian fungus parasite. This leaves ash as the commonest remaining tree; the United States has spent millions of dollars in a vain attempt to keep out an Asian insect that destroys it. Such a story can be repeated in many other countries. At this rate, how much will be left in another hundred years?

Tropical Gardening

Tropical gardeners of Southeast Asia domesticated a great many plants as early as 8500 BCE—such as rice, cane sugar, citrus fruit, bananas, coconuts, and yams—some of which still play a significant part in feeding humankind in far-flung parts of the Earth. Tropical gardeners survive today, like hunters and gatherers, only in a few refuges where they have not been invaded and conquered.

Tropical gardening of the kind that is still practiced in the interior of New Guinea is probably very old. When outsiders discovered New Guinea gardens (and a society of gardeners) in the 1930s, each agricultural village was independent, and each family lived on food their members raised on small plots of land. Population was dense enough to occupy almost all suitable soils, and warfare between rival communities was common. Crops were various: mainly roots that could be reproduced by replanting the top of a growing plant whenever it was pulled from the ground to provide the next meal. As long as part of the root was still attached, the top could then regrow a new root and in a few months provide the gardeners with yet another meal. New Guinea gardeners also grow many other kinds of plants to supplement starchy roots like yams and taro, both of which were poisonous when fresh and had to be boiled in water to dissolve the acrid chemicals that protected them from insects—but not from humans.

A few tropical gardeners also survive in remote mountainous areas of the southeastern Asian mainland, and once existed throughout south China as well, where rice was one among the many different crops they harvested as early as 8500 BCE. But the

gardeners of southern China proved incapable of resisting encroachment from the north by Chinese armies and settlers who learned how to raise rice and made it the staple food of historic China by about 500 BCE, even though millet and wheat, upon which Chinese society had depended earlier, continues to prevail in the northwestern-most Chinese provinces.

From what we now know about tropical gardeners in contemporary New Guinea and in ancient China it is reasonable to suppose that this kind of gardening originated along the coasts of the monsoon seas soon after humans first learned to fish on rafts and in boats and then made permanent settlements along the shoreline where safe harbor could be found. Hunters and gatherers undoubtedly knew a lot about plants from the very beginning of human history, and women left behind by early fishermen had every inducement to transplant useful plants to the places where they had settled down, thus becoming the first gardeners. Fruit and nuts from trees (coconuts, citrus, bananas, plantains, and sugar cane), as well as roots (and grasses like rice)—all probably came under human management in these gardens. Since we know that humans crossed at least 96.5 kilometers (60 miles) of open water to reach Australia sometime between 60,000 and 40,000 years ago, fisherman on rafts and/or boats, complete with paddles and sails, would have also traveled on the adjacent monsoon seas that long ago. Those seas were especially hospitable to early sailors, since the monsoon winds blow equably in opposite directions for part of each year and make even lengthy coastal voyages comparatively safe.

But direct evidence is lacking for what probably was by far the oldest form of agriculture, and there is scant hope that archaeologists will ever be able to

find traces of boats, tropical gardens, or any other elements of early coastal settlements because, beginning about 16,000 years ago, Ice Age glaciers began to melt, whereupon sea levels rose and submerged the coastlines of the Earth. Whatever slight traces coastal tropical gardeners in Southeast Asia may have left are therefore now deep under water. To be sure, inland lakes and streams might have attracted similar settlements, but so far archaeologists have found only very slender traces of tropical gardening far away in south China where fishing and sea going played no part.

Wherever such communities existed, they were always vulnerable to civilized encroachment. When each family raised its own food and did not have to store large quantities of harvested grain, everyone lived more or less like everyone else. In such communities priests could not persuade ordinary people to give part of their harvest to the gods in order to assure divine protection from disaster, and specialized fighting men could not demand a share for themselves in return for protection against raiders from afar. But grain farmers were liable to both these forms of blackmail, and thereby inaugurated what we call civilization, with an array of specialized traders, artisans, soldiers, and priests—and before long tax collectors, standing armies, and hereditary rulers. Such complex societies easily overwhelmed independent and equal villagers whenever they encountered them. So tropical gardeners survive today, like hunters and gatherers, only in a few refuges where civilized peoples have not chosen to invade and conquer them.

Yet in their time tropical gardeners of Southeast Asia domesticated a great many plants, some of which still play a significant part in feeding civilized

humankind in far-flung parts of the Earth—rice first and foremost, but cane sugar, citrus fruit, bananas, and coconuts, as well yams and other roots. Such domestication constitutes tropical gardening's ongoing contribution to humankind as a whole.

Túpac Amaru

(c. 1742–1781)

PERUVIAN REVOLUTIONARY

Although the massive rebellion he led in 1780 against Spanish colonial authority was ultimately suppressed, the Peruvian revolutionary Túpac Amaru, a descendant of the ruler in power during the conquest of the Inca capital at Cuzco in 1533, has become an iconic figure in the struggle for indigenous rights in Peru.

In 1780 Túpac Amaru (José Gabriel Condorcanqui), an indigenous ethnic lord or *kuraka* in the region near Cuzco in the Peruvian highlands, led the largest and most serious rebellion in South America against Spanish colonial authority in the period between the sixteenth-century wars of encounter and conquest and the early nineteenth-century movements toward independence. Centered in a rural region near the old Inca capital of Cuzco, especially in the provinces of Canas y Canchis (Tinta) and Quispicanchis, where Túpac Amaru and much of his family lived, this rebellion quickly engulfed the southern highland region of the Viceroyalty of Peru from Cuzco to Lake Titicaca and beyond. Other uprisings in what is now Bolivia (at that time the Viceroyalty of Río de la Plata) have become associated historically with the Túpac Amaru rebellion even though at least one of them began before the Cuzco movement. In the region between Sucre and Potosí, several members of the Katari family led local villagers in a movement that challenged the colonial order at both the village and governmental level. To the north, near La Paz, Julián Apasa, who looked to the leaders of the other two rebellions to form his *nom de guerre*—Túpac Katari—fought on his own and with the forces of the Túpac Amaru rebellion to break Spanish control in that region.

Túpac Amaru's father died when he was young, and his uncles and the local priest raised him. He also studied at the Jesuit school for indigenous nobility in Cuzco. He ran a business of transporting goods throughout the southern Andes and he also had interests in mines. He got along well with most priests and with the bishop of Cuzco. His relationship with local Spanish officials was much more stormy, but it too varied from individual to individual. Túpac Amaru—actually Túpac Amaru II—was descended from Manco Inca, the Inca ruler who rose in rebellion against the Spaniards shortly after their taking of Cuzco in the 1530s and who established a neo-Inca state in Vilcabamba. Also among his ancestors was Túpac Amaru I, Manco's son and the last leader of the Vilcabamba resistance.

Túpac Amaru II pressed the Spanish courts to be recognized as heir to the Inca throne. Two factors worked to feed belief in the return of the Inca to power: the works of Garcilaso de la Vega glorified the rule of the Inca, and the myth of Inkarrí spread. According to the Inkarrí myth, the body of the Inca ruler was regenerating from his buried head (the first Túpac Amaru had been beheaded by the Spanish after surrendering), and when the process was complete he would reemerge to reestablish the more just rule and social order that had existed before the arrival of the Europeans.

Colonial Oppression

At the time Túpac Amaru was voicing his claims, Andean indigenous society was suffering from the changes the Spanish crown was making in the colonial structure. In the eighteenth century, Spain, like

If no man could become rich in Peru, no man could become poor. • William Prescott (1726–1795)

other European powers, tightened its control over its colonial possessions. In the Spanish realm this meant, among other changes, making a determined effort to restructure the colonies so they would be more lucrative for the mother country. In the Andes there was an effort to increase the efficiency in collecting tribute and sales taxes were not only increased but also imposed on some items produced by indigenous people that had previously been exempt. In addition, some items that previously had not been taxed became subject to increasing taxation and customs houses were established to ensure collection of these duties. This disrupted trading and exchange in the southern highlands, as did the creation of the Viceroyalty of Río de la Plata, which took over control of much of the region that later rebelled.

At the same time, local Spanish authorities known as *corregidores* pressed the indigenous population ever harder after the informal forced sale of goods was legalized. *Corregidores* often abused their colonial right to force the sale of goods by doubling or even tripling the established quotas. This practice aroused the ire of many indigenous people, some of whom began to balk at such excessive economic coercion.

Parallel to these changes, the indigenous population was finally starting to grow after the terrible decline caused largely by the epidemics of Old World diseases that devastated the New World well into the eighteenth century in the Andes. Thus, just as the colonial government was increasing its demands, the indigenous peoples were seeing their per capita resource base shrink as villages once again were teeming with people. This conjunction of international, regional, and local circumstances increased tensions and created a climate in which a rebellion might gain hold.

Rebellion and Aftermath

The combination of messianic hopes, deep discontent over the current political situation, and the presence of a leader created a conjuncture in which rebellion erupted. Spreading like wildfire over the southern highlands of Peru and Bolivia, the rebellions of the

early 1780s shook colonial society to its foundations and led to some 100,000 deaths. Túpac Amaru was captured when the rebellion was just a few months old and he and much of his family were executed in a most brutal manner in the plaza of Cuzco while other family members were exiled. Despite the suppression of the rebellions they led, however, Túpac Amaru, Túpac Katari, and the Katari family had all given direction and voice to many of the exploited peoples of the Andes, who under increasing pressure risked everything to end their exploitation and establish a more just rule under a system that would be culturally meaningful to them. In the short run the rebellion put a fear into the dominant society that increased the distance between the races in Peru. Over the longer haul the image of Túpac Amaru as a harbinger or symbol of social justice has emerged. The left-leaning military government of Velasco used his image and rhetoric from the rebellion to promote social change in the late 1960s, the dream of Inkarrí lives on, and the Túpac Amaru revolutionary movement of recent times obviously chose him as their symbol because of what he means in the minds of many ordinary Peruvians today.

Turkic Empire

The Tüürks created a vast empire in Eurasia that dominated the nomadic steppe zone and adjoining lands of sedentary civilization, from Manchuria to the Black Sea, during the mid-sixth to mid-eighth centuries. It was the first of the great, trans-Eurasian empires and was surpassed in size only by the Mongol Empire of the thirteenth century, which in many respects was built on Türk traditions of governance.

The name “Türk” was a political designation adopted by other Turkic-speaking peoples during the period of the Türk Empire from the mid-sixth to the mid-eighth centuries. The Tüürks’ neighbors (who were the geographers and historians of the Muslim world) used it to denote the Turkic-speaking peoples with whom they came into contact from the latter half of the seventh century onward. Most of these peoples had been part of the Türk state. The term “Türk” survives today as the ethnonym of the dominant ethnic grouping of the modern Turkish state and has been used as an ethnic designation for other Turkic peoples.

Origins

Türk origins remain obscure. Their language, first recorded in a series of inscriptions in the Orkhon river region, the center of their state in present-day Mongolia, belongs to the Altaic language family, which consists of Turkic, Mongolic, Manchu-Tungus, and possibly Korean and Japanese. There has been much debate over whether these language groupings are related genetically or have converged due to long periods of contact and borrowing. There can be little doubt that the Tüürks emerged from Mongolia and southern

Siberia, the westernmost region of the Altaic peoples, who were largely in Manchuria. The Tüürks’ immediate neighbors to the west and northwest were Iranians (in western Mongolia) and the Uralic peoples of Siberia.

The Tüürks, under this name, emerged onto the stage of history only in the mid-sixth century. Various Turkic-speaking peoples had earlier been part of the Xiongnu (Asian Hun) Empire (c. 209 BCE–mid-second century CE), of still undetermined ethnic origins. Some Turkic groupings migrated or were pushed westward to the steppes of present-day Kazakhstan and the Volga–Black Sea region as a result of warfare between the Xiongnu and the Chinese. The migrants were incorporated into the polity of the European Huns, whose relationship with the Xiongnu remains the subject of much debate. These early migrations initiated a movement by Turkic peoples from the Chinese borderlands to the western steppes that continued for more than a millennium. Later empires in Mongolia, such as the Rouran (Asian Avars, early fourth century CE–552 CE), drove other Turkic groupings westward into the Black Sea steppes by around 463. None of these peoples called themselves Tüürks.

The Orkhon inscriptions tell us nothing of Türk origins. Contemporary Chinese accounts, which state that they derived from “mixed Xiongnu,” record a variety of ethnogenic tales reflecting, in all likelihood, the diverse origins of the core peoples that constituted the tribal union the Chinese called “Tujue.” The name *Türk* does not appear until the Chinese accounts relate the foundation of their state in the mid-sixth century. The Chinese sources also note their ruling clan (or tribe) as the Ashina and place some of the latter’s early (fifth-century) history in the Gansu-Xinjiang region of northwestern China, areas that were then

populated by Tokharian and Iranian peoples. The name “Ashina” appears to derive from an Iranian or Tokharian term and is noted in an inscription written in Sogdian (the principal language of the Silk Roads) dating to 582, the earliest inscription known thus far from the Türk Empire. Here, the Ashinas are paired with the Türks, perhaps indicating that they were still two distinct entities at this time. The Orkhon inscriptions subsequently make note of the *Kök Türk* (in Turkic, *kök* means “sky, sky-blue”) which may refer to this earlier distinction. The color blue was associated with the direction east in Inner and East Asia. Hence, *Kök Türk* may also mean “Eastern Türks” or even “Heavenly Türks” (as it has sometimes been rendered). None of the names of the early Türk *qaghans* is of Turkic origin (*qaghan* is the Inner Asian title for “emperor” first noted in the third century CE).

Formation of the Türk Empire

The Türks came to prominence as the older states around them were crumbling. The Tuoba Wei dynasty (386–534 CE), a semi-Sinicized dynasty of Altaic origins that had controlled much of northern China, had divided into two warring rival states: the Eastern Wei (534–550), which was replaced by the Qi (550–557), and the Western Wei (535–557), which was replaced by the Northern Zhou (557–581). In Mongolia, the Rouran (or Avars) were increasingly caught up in internal dynastic strife and periodic revolts of vassal peoples. Among the latter were the Türk-Ashina, peoples who engaged in metalworking for their Rouran overlords. The Rouran *qaghan* Anagui (520–552) made an alliance with the Eastern Wei. The Western Wei retaliated in 545 by opening communications to Bumīn, the Türk-Ashina leader. When Bumīn was refused a Rouran royal bride as reward for his role in suppressing a revolt of the eastern Tiele (a large union of Turkic and Mongolic tribes that extended from northern Mongolia to the Pontic steppes in present-day Ukraine) in 551, the Western Wei sent off a princess to him, thereby cementing their ties. Bumīn destroyed the Rouran in 552 and took over their empire. A program of conquest immediately followed.

While Bumīn (who died shortly after this) and his sons Golo (d. 553) and Muqan (or Mughan; reigned 553–572) consolidated their control in Mongolia, his brother Ishtemi (reigned 552–c. 576) extended Türk power to the western steppes and the Crimea, laying the foundations of the western Türk Empire. Following old steppe principles of governance, the Türk Empire was divided in two for administrative purposes. The supreme *qaghan* resided in the East; his counterpart in the West had slightly less power. Their subjects now included the Sogdians who were the principal merchants of the Silk Roads, various other Iranian sedentary and nomadic peoples of Central Asia, and a number of Turkic tribes that had earlier migrated westward.

Allied with the Sasanid Empire of Iran, Ishtemi crushed the Hephthalite state (in modern Afghanistan), which derived from a mix of Asian Avar and Hunnic elements, around 557. At about this same time, a people calling themselves Avars, who had fled the Türk conquest, made their appearance in the Pontic steppes and opened diplomatic relations with Byzantium. The Türks under Ishtemi soon appeared, and the Avars, accompanied by some subject tribes, retreated to Pannonia (modern Hungary). Türk power now extended from Manchuria to the Crimea. The Avars remained safely ensconced in Pannonia until their state was destroyed by the Franks of Charlemagne at the end of the eighth century. They frequently raided Byzantine holdings in the Balkans, often in conjunction with the Slavs, substantial groupings of which began to settle in the region, giving rise to the Southern Slavic peoples of today.

The Türks, having conflicting trade and political goals with Iran, broke with the Sasanids and established relations with Constantinople in 568. Byzantium, having recently established its own silk industry and no longer as dependent on the Silk Roads and Iran for this luxury good, was nonetheless anxious to have allies against Iran. The Türks were seeking an outlet for the silk that they were getting from China. The resulting Byzantine-Türk alliance did not work smoothly, the Türks often berating Constantinople for having dealings with their “runaway slaves,” the Avars.

The First Qaghanate: East (552–630 CE) and West (557–659 CE)

The Türks were able to exploit the political fragmentation of northern China, whose competing dynasties were only too willing to buy the Türks off with silk and trading privileges. The zenith of Türk power was reached during the reign of Taspar (or Tatpar, reigned 572–581), Muqan's younger brother. Thereafter, China, reunited under the Sui dynasty (581–618), regained the military upper hand. This coincided with increasing strife among the ruling Ashina. The Sui skillfully exploited these internecine disputes and encouraged revolts by subject peoples of the Türks. In the west, Tardu (d. c. 603), Ishtemi's son, trying to exploit the rivalries of his eastern cousins, made a bid for supreme power. Although his army was badly defeated around Herat by the Sasanid general Bahrâm Chôbîn of Iran in 589, Tardu recovered and by the late 590s was on the verge of realizing his ambitions. The Sui, however, instigated a massive revolt of the subject tribes, in particular the Tiele union, and Tardu disappeared from view. When the Sui overextended themselves with military ventures against Koguryo (in Korea), the Türks briefly revived. The Sui were swept from power by the Tang dynasty (618–907), themselves of probable Altaic origin and long familiar with the northern frontier zone. The Tang, like the Sui, capitalized on Ashina internal bickering and in 630 brought the eastern Türks, exhausted also by natural disasters, under their control. They were settled within China's borders and the Ashina and clan nobles were taken into the ranks of the Chinese military service.

Tardu's successors in the west fared better for a time. In the 620s the Byzantine Emperor Heraclius (reigned 610–641) used Türk forces under the western *quaghan*, Tong Yabghu Qaghan (618–630), to defeat the Sasanids in 628. Tong Yabghu, however, was assassinated by an uncle, and the western Türks divided into two rival factions, the Dulu and Nushibi, together termed the On Oq ("Ten Arrows"). They succumbed in 659 to Tang armies that ventured deep into Central Asia. The more westerly groupings of the Türks formed the Khazar state (c. 650–c. 965), which encompassed

This miniature painting with calligraphy depicts Turkic troops in battle and was once owned by Abdülaziz, Sultan of the Türks, 1830–1876. New York Public Library.

the Volga-Ukrainian steppes, the North Caucasus, and elements of the Eastern Slavs and Finno-Ugric peoples. The Khazars were the main obstacle to Arab advance beyond the North Caucasus.

The Second Qaghanate: East (682–742 CE) and West (c. 700–c. 766 CE)

Although the Tang preserved the eastern Türks, planning to use them as part of their border defense system against other nomads, the Türks proved to be recalcitrant subjects. The eastern Ashina Qutlugh (682–691), with a small band, rallied the Türks and reestablished the qaghanate in 682, taking the throne name Ilterish. He and his brother and successor, Qapaghan Qaghan (reigned 691–716), ably assisted by their chief counselor, the Chinese-educated Tonyuquq, reestablished their hold over the Inner

Asian nomadic and forest peoples. In the words of the Orkhon inscriptions, they “made the poor rich and the few many” (Tekin 1988, 12). This was achieved through continual warfare, memorialized in the Orkhon inscriptions, against their frequently rebellious subject tribes, a policy that his successor, Bilge Qaghan (reigned 716–734), aided by his brother Köl Tegin (d. 731), was forced to continue due to ongoing resistance to Türk rule. Bilge Qaghan was poisoned, most probably by someone within his entourage. Thereafter, the familiar pattern of dynastic bickering led to the destruction of the eastern Türk Qaghanate in 742 by a coalition of subject tribes who were overthrown in turn by the Uygurs, another Turkic-speaking Central Asian people.

Meanwhile, the western Türks (under eastern Türk domination by 699) faced a growing threat from the Arabs. What had begun as Muslim raids in the late seventh century became a more systematic program of conquest under Qutaybah ibn Muslim (d. 714), a general in the service of the Arab Umayyad dynasty (661–750). Moreover, China and Tibet (now a major player in Central Asian affairs) were active in the region. Internecine Arab strife allowed the western Türks to maneuver between China, Tibet, and the Arabs. The On Oq union, however, continued to face problems of political instability. The Turkic Qarluqs, a vassal subconfederation of the eastern Ashina, fled to the western Türk lands around 745. When the Arabs and the Chinese clashed on the Talas River (751, in Kazakhstan), the Qarluq defection to the Arabs proved decisive. But China’s Tang dynasty soon was caught up with domestic rebellions (the An Lushan Rebellion in 755) and the Arabs, who were seeking to consolidate their hold over Sogdia and Khwarazm, withdrew from the steppe. By 766 the Qarluqs had made themselves masters of the western Türk steppes.

Governance, Religion, and Society in the Turkic Empire

The Turkic Empire followed the steppe imperial traditions first clearly articulated by the Xiongnu. The Rouran were probably the immediate source for many of the titles associated with high office. Most of these

titles were of foreign origin (Iranian, Tokharian, Indian, Chinese). Typical of the steppe tradition, the Türks adhered to the notion of the collective sovereignty of the ruling clan over the whole of the empire. Any member of the Ashina could claim rule. An attempt to work out an orderly system of lateral succession (from brother to brother and thence to their sons) proved unworkable. Conflict often preceded, accompanied, and followed the elevation of a new *qaghan*. Qaghanal investiture involved elaborate rites, including the ritual strangulation with a silk cord of the new *qaghan*, who in a shaman-like trance, then stated the length of his reign. The *qaghan* was often described as heaven-like or God-like, indicating an ideology that stressed his sacral as well as temporal power. Upon his death, the *qaghan* “returned to the gods” (Moriyasu and Ochir 1999, 124). Nonetheless, the failure to work out an orderly and conflict-free system of succession proved fatal to the empire.

The Türks worshipped Tengri, a supreme celestial deity also worshipped by the Mongols, and they were also practitioners of shamanism. There are scattered references to Umay, a goddess of fertility, as well as to holy mountains, forests, and other refuges. Earth, water, and fire were also worshipped, and ancestor worship was practiced. Some of the early *qaghans* were also attracted to Buddhism. This and other religions came to the Türks through the Sogdians, who also brought them writing systems based on the Aramaic-Syriac alphabets. One or more of these alphabets were probably the source of the runic scripts that spread across Turkic Eurasia. The Orkhon inscriptions, carved by Chinese artisans, were written in one of the variants of this runic script.

The Türks brought under their rule a wide range of Turkic and other Altaic peoples, Iranians, and Uralic and Paleo-Siberian peoples. The steppe peoples practiced pastoral nomadism, and the Türks continued to live in felt tents and consume a diet that was high in dairy products (including fermented mare’s milk) and meat. For other goods they relied on trade or raiding the neighboring sedentary states, especially China. They were vitally interested in trade, and with their Sogdian vassals they played a major role in the unification of the Silk Roads, one of the major arteries of East–West

Map of the Turkish Empire, by John Speed. 1626. This highly decorative map shows eight city views in a banner across the top and ten costumed figures on the left and right sides.

commerce in the medieval world. Their empire also set the pattern for subsequent steppe empires.

Tutu, Desmond

(b. 1931)

SOUTH AFRICAN CLERIC AND OPPONENT OF APARTHEID

Because he is one of the world's most passionate nonviolent activists against apartheid in South Africa, Desmond Mpilo Tutu's name is synonymous with the struggle against that racist movement. He has served the Anglican Church in a number of roles culminating in archbishop, and continues to make international appearances on behalf of racial equality.

Desmond Mpilo Tutu, a leading opponent of South Africa's racist apartheid system, became chair of the South African Truth and Reconciliation Commission after the fall of the apartheid regime. He has received numerous honorary degrees and awards, including the 1984 Nobel Peace Prize. An Anglican priest, Tutu also served the church as a chaplain, curate, theologian, dean, bishop, and archbishop, and as general secretary of the South African Council of Churches.

Desmond Mpilo Tutu was born in Klerksdorp, Transvaal, South Africa. After receiving his high school diploma in 1950, he earned his teacher's diploma from Pretoria Bantu Normal College in 1953 and his BA from the University of South Africa in 1954. He then taught high school for four years, during which time he met and married his wife Leah, with whom he had three daughters and a son. As Tutu began his teaching career, everyday life for the majority black population in South Africa was drastically changing for the worse. In 1948 a white minority government implemented the comprehensive system of racial segregation, disenfranchisement, land alienation, and oppression known as apartheid. Under apartheid, white student education was well funded and of a high quality, while blacks were forced to

attend inferior schools, study restricted curriculums, and had limited access to higher education and job opportunities. Tutu quit teaching in 1958 to protest this unjust educational system.

An early influence in Tutu's life was the Anglican bishop Trevor Huddleston, an early and tireless opponent of apartheid who inspired Tutu to enter the ministry. Ordained an Anglican priest in 1961, Tutu then traveled to London, where he earned bachelor of divinity honors and master of theology degrees. Returning to South Africa in 1966, Tutu taught theology at black universities before becoming associate director of the World Council of Churches, based in London, in 1972. In 1975 he became the first black African named Dean of St. Mary's Cathedral in Johannesburg. He held this position for only a year, however, before becoming bishop of Lesotho, where he served until 1978. He then became the first black African to be installed as general secretary of the South African Council of Churches (SACC).

In 1976 black students in townships across South Africa, most notably in Soweto near Johannesburg, erupted in protest against new apartheid laws that severely affected the already inferior black educational system. Tutu's position as SACC general secretary and his ability to speak publicly at a time when most black South African leaders were in jail or otherwise silenced offered him a unique platform from which to criticize the apartheid system. He soon became an internationally respected figure as he exposed apartheid's evils. When he called for economic sanctions against South Africa, the apartheid government withdrew his passport, but had to restore it again in 1982 under international pressure.

Archbishop Desmond Tutu. Photo by Benny Gool.

Tutu's peaceful but insistent campaign against racial injustice in South Africa earned him the Nobel Peace Prize in 1984. The Nobel Committee's announcement cited "Tutu's role as a unifying leader figure in the campaign to resolve the problem of apartheid in South Africa. The means by which this campaign is conducted is of vital importance for the whole of the continent of Africa and for the cause of peace in the world" (Nobel Foundation 2004).

Tutu left his post as SACC General Secretary in 1985 and became a leader in the United Democratic Front, a multiracial mass movement that sought to overturn the apartheid system peacefully. The movement realized its goal in 1994 when Nelson Mandela (b. 1918), a leader of South Africa's main black political party, the African National Congress, became the

first democratically elected President of South Africa. The following year Mandela appointed Tutu chair of the Truth and Reconciliation Commission, an unprecedented effort by South Africans to come to terms with their recent, dark past. The Commission focused on political crimes and human rights violations committed between 1960 and 1994, offering immunity to those who confessed their guilt. The Commission's report, issued in 1998, documented more information about political crimes and victims than any similar endeavor in world history. Although the Commission's work was highly controversial, Tutu maintained throughout the hearings a deep spirit of forgiveness and understanding rather than revenge. Tutu has often referred to the African concept of *ubuntu*, which includes the ideals of human brotherhood, mutual responsibility, and compassion.

Following his work with the Truth and Reconciliation Commission, Tutu went to Atlanta, Georgia, in 1998 to teach at Emory University. In 2000 he returned to South Africa, where he continues, as always, to fight for political, economic, and social justice for all the world's peoples. Like Gandhi, Martin Luther King Jr., and the fourteenth Dalai Lama, Tutu is a courageous practitioner of nonviolent activism against injustice and oppression. His thirty-year nonviolent campaign against apartheid, and the compassion and strength he displayed in healing wounds and uniting peoples during the Truth and Reconciliation Commission hearings, have given him a unique place in world history.

Ugarit

Archaeological finds from the ancient cosmopolitan trading center of Ugarit, which flourished on the Syrian coast from about 2000 to 1200 BCE, reveal much about the city's language, culture, government, and economy—as well as aspects of life in the larger Mediterranean world. One of history's unresolved mysteries surrounds the virtual abandonment of this strategically vital site after 1190 BCE.

Ugarit is the name of an ancient urban center located on the Syrian coast. The contemporary Arabic name for the site is Ras Shamra (Fennel Cape). It was a cosmopolitan center of trade during the Middle Bronze II and Late Bronze periods (2000–1550 BCE and 1550–1200 BCE, respectively), with an ethnically diverse population. Since 1929 many texts written in Hurrian, Akkadian, Sumerian, and Ugaritic (the native language of the city's inhabitants), have been discovered within its environs. Significant archeological discoveries have also been made at Minet el-Beida (west of the city on the coast), believed to be its port, and at Ras Ibn Hani, located some 4.5 kilometers to the south. The archeological record indicates that Ugarit was first occupied in the seventh millennium BCE and enjoyed its cultural zenith from the fourteenth through the thirteenth centuries BCE, from the time of the reign of Niqmaddu II (reigned c. 1350–1315 BCE) through the reign of Ammurapi (reigned c. 1215–1190/1185 BCE). During this time, the city was the center of a kingdom whose territorial expanse—at its height—was roughly 5,425 square kilometers. Extant evidence suggests that the city was destroyed around 1190 BCE by an invading force from the eastern Mediterranean region. Ugaritic

documents identify the invaders as the “Shikila people,” part of the larger group of “sea peoples” known to have attacked the Egyptian and Hittite kingdoms during the same period. After its destruction, the site was occupied only sparingly during the fifth to fourth centuries BCE and the first century BCE. One of history's unresolved mysteries surrounds the virtual abandonment of this strategically vital site after the twelfth century BCE.

At its cultural high point, the population of Ugarit and its surrounding kingdom reached thirty-one thousand to thirty-three thousand persons; about six thousand to eight thousand of them lived in the city proper, with another twenty-five thousand occupying a vast array of rural villages surrounding it. It was one of several independent coastal Levantine (referring to the eastern Mediterranean) city-states that flourished during the Middle Bronze II and Late Bronze Periods. The city's location on a land bridge of strategic importance to these kingdoms, several of which had colonies and imperial holdings throughout the Near East, had a profound impact on its history. During this time the city enjoyed a high degree of prosperity due in large part to favorable climactic conditions and its leaders' ability to negotiate political arrangements with the city's powerful neighbors. Such important arrangements included the establishment of détente with Egypt, the formation of a protective alliance with the Amurru kingdom located to its immediate south, and eventual accession to vassalage under the Hittite Empire located to its north.

The city's native language, Ugaritic, has affinities with Hebrew and other Canaanite dialects and is part of the Afroasiatic phylum. It is written in an alphabetic cuneiform script consisting of thirty signs.

Ugaritic writing is almost strictly consonantal. Vowels are indicated very sparingly. Future study of this language and its script is likely to shed additional light on the development of writing systems in Phoenicia and Greece. It also promises to help us better understand the history of literacy in early and late antiquity. The corpus of Ugaritic literature consists of a rich and varied assortment of genres. The major edited collection of these texts (KTU) has identified literary and religious texts, letters, legal texts, economic texts, scribal exercises, and inscriptions on objects, as well as some texts that are unclassified and others that are illegible or fragmentary.

Ugarit was historically a prosperous and politically stable city governed by a single dynasty. Although less than half of the site has been fully excavated, evidence of intricate urban planning, with particular attention to public works, including city walls, streets, water works, and sewage facilities, has been found. Intensive agriculture and international trade via land and sea fueled the city's economy. Cereals, grapes, and olives were grown. Stone was quarried, timber was harvested, and both cattle and sheep were raised. Given its proximity to the coast, fishing may well have been one of its mainstays. Industrial activities within the city and at its port included the manufacture of purple dye, textiles, pottery, household utensils, luxury items (metal and precious stones), and weapons. Slavery was also permissible.

Ugarit's monarch shared power with a prefect, queen, and nobles. Members of the royal family also exercised some influence in the determination of affairs of state. Its society was stratified, though not in a rigid manner. Vertical and horizontal movement was possible. Although it was a patriarchal society, women were afforded a number of rights and privileges. They could inherit family property, if so designated by the appropriate male head of household (i.e., a father or husband), designate heirs, initiate proceedings for divorce and adoption, purchase and dispense of property, and retain control of the possessions brought into a marital arrangement in the event of dissolution.

The populace was separated into two large classes. The first consisted of "men of the king." These were craft specialists, warriors, and members of other elite groups retained by the monarch for service to the crown. The second was made up of the members of the general populace, whose affairs were governed by familial norms and local customs enforced at the community level by councils of elders. The Ugaritic social hierarchy was extraordinarily complex and contained an array of military, scribal, and administrative classes.

Extended family units consisting of parents, children, and other relatives appear to have been the norm. Furthermore, one's family consisted of members both living and deceased. Thus, proper exercise of familial obligations included veneration of one's ancestors. Along with the worship of familial deities, ancestor veneration appears to have been an essential feature of Ugaritic religious life. Ugaritic theology was polytheistic. In excess of a hundred gods are mentioned in various pantheon lists and other sources. Chief among these are El and Asherah (the divine regent and his spouse), Baal (the storm god and coregent), Anat (warrior, member of the divine royal household, and sister of Baal), Yamm (the deified ocean and major rival of Baal for cosmic coregency), and Mot (the god that embodies the forces of death and dissolution in all of their cosmic and earthly manifestations). Two large temples and a rich assortment of ritual texts have been excavated that provide evidence of a complex religious hierarchy with several levels of functionaries including administrators, priests, and other officials.

Ugaritic expressive culture was also highly developed. The achievements of the city's artists in the areas of music, architecture, sculpture, and folklore are noteworthy.

In sum, data from Ugarit tell us a great deal about life in ancient Syria. Its material artifacts, texts, and history are also of particular interest to philologists, anthropologists, and other scholars of antiquity because of the light that its language, lore, and culture shed on developments in the larger Mediterranean

world as well as in Anatolia, Syria-Palestine, Mesopotamia, and Egypt.

‘Umar ibn al-Khattab

(c. 586–644 CE)

SECOND MUSLIM CALIPH

After the Prophet Muhammad, ‘Umar ibn al-Khattab was one of the most influential rulers during Islam’s formative years. He was responsible for the first codification of Islamic law, for devising the Islamic calendar, and for many of Islam’s more proscriptive ordinances and attitudes.

One of the ten Companions of the Prophet to whom Muhammad promised paradise, ‘Umar ibn al-Khattab ruled from 634 CE to 644 CE as the second of the four Rashidun (Arabic: “rightly guided”), or universally acknowledged, caliphs. (‘Umar’s daughter was Hafsa, one of Muhammad’s wives.) After Muhammad, ‘Umar is one of the principle personalities of Islam, having presided over a crucial era in Islam’s political and doctrinal formation, playing a role analogous in many ways to that of Saint Paul in Christianity.

An early convert to Islam, ‘Umar took part in the Hijra of 622 CE that marked the flight of Muhammad from Mecca and the establishment of the first Muslim community at Medina. Becoming caliph following the death of Abu Bakr, (c. 573–634 CE; reigned 632–634 CE) and assuming the title of commander of the faithful, he governed the Arabs during their most dramatic period of military expansion, which included the conquests of southern Iraq (from 635 CE), Palestine (638 CE), Syria (637 CE), western Iran (from 641 CE), Egypt (642 CE) and Libya (643 CE). Among the many important administrative developments credited to his reign are the first codification of Islamic law, the devising of the Islamic calendar, and the establishment of the Islamic magistrate that registered the Muslims of Medina and Arab soldiers, among whom

the booty from the conquests and the tribute they generated was to be formally shared. Allotments were based on one’s tribal pedigree and the length of one’s family’s association with Islam. As much a system of control as reward, it was intended to maintain the cohesiveness and distinctiveness of Arab identity in the face of geographic dispersal, a tendency manifest also in ‘Umar’s policy of establishing Arab-only garrison towns in conquered areas to prevent religious and cultural contamination by the conquered peoples.

He is most famous among non-Muslims for the so-called Pact of ‘Umar, which is held to mark the first formal elaboration of the protection extended in principle to all conquered peoples who were adherents of revealed religions. The designation “People of the Book” originally applied only to Christians and Jews, but was soon extended to include Zoroastrians, eventually Buddhists, and in some cases members of other religions in accord with the necessities of governance. The origin of the pact is said to be negotiations that ‘Umar carried out with the people of Jerusalem sometime between 636 CE and 638 CE, around the time of their surrender. The Islamic conception of the city as a holy site was coalescing at this time. ‘Umar is said to have entered messiah-like on a donkey; he eschewed an offer to pray in the Church of the Holy Sepulchre on the grounds that Muslims would later demand it be destroyed to make way for a mosque. Indeed, the spot nearby where he is said to have prayed is the site of the present Mosque of ‘Umar.

By allowing non-Muslims wide liberties and permitting them to continue to administer the conquered lands, ‘Umar confronted two serious challenges to instability resulting from the incredible pace of the conquests and the paucity of Arab military forces:

The death of a thousand worshipers is easier to bear than the death of a scholar who has knowledge of what Allah has permitted and forbidden. • 'Umar ibn al-Khattab (c. 586–644 CE)

namely, the potential for popular unrest and rebellion and the necessity to maintain the economic viability of the new territories. Although the various rough surrender agreements were undoubtedly negotiated ad hoc by local commanders, ninth-century and later Islamic jurists conceived of an elaborate and standardized pact, which they then attributed back to 'Umar himself. In a less tolerant vein, 'Umar originated the policy that the Arabian Peninsula itself should be inhabited solely by Muslims, and Christians and Jews were expelled. His attitude to gender role was also famously inflexible and many of the more restrictive Islamic traditions in this regard can be traced to his influence.

'Umar was choleric and uncompromising, his formidable character and famous ill-temper stifling opposition. In the finest Machiavellian style, he played off potentially dissenting elements among the Companions of the Prophet and the tribal leaders, depending as much as he could on officials and lieutenants of his own making, all the while supporting the power of the Meccan elite, particularly the future caliphal family, the Umayyads.

On 3 November 644 CE 'Umar was murdered by a Christian slave belonging to the governor of Basra (in southern Iraq), who was apparently distraught at having failed to negotiate fiscal concessions from the caliph. After his death, the Meccan elite continued to dominate the caliphate, electing another of their group, 'Uthman ibn 'Affan, as successor—a fact

that would exacerbate divisions in Islam between the Syrian-Meccan faction and the Iraqi faction, which tended to support the claims of 'Ali (c. 600–661 CE), the fourth caliph.

'Umar is intensely revered and romanticized, particularly by Sunni Muslims. Famous for the strength of his convictions and unwavering rigor, he is considered by many to be the originator of many of Islam's more proscriptive ordinances and attitudes.

United Nations

At the end of World War II in 1945, the United Nations was established with the aim of preventing further devastating wars. It is a member-based international organization open to all legitimate sovereign states in the international community. While it has a broad and expanding mandate that changes with the times, maintaining international peace and security remains a central aim.

The United Nations (U.N.) is both an international organization and a transnational association of countries. Its primary mission is to maintain world peace and security and promote social development and human rights. The U.N. was officially established by fifty-one nations on 24 October 1945 in response to the catastrophes of the two world wars, and met for the first time in Westminster Central Hall in January 1946.

The U.N., which emerged from years of intense debate tainted by the failure of the League of Nations during the interwar period, was founded on many of the conclusions reached at the 1944 Dumbarton Oaks conference in Washington, D.C., which was attended by representatives of China, the Soviet Union, the United Kingdom, and the United States. The U.N. promised to end the dominance of feuding empires and imperialism—the results of which were the social and economic devastation of the two world wars—and to order the world based on statehood, national sovereignty, and the stability believed to be associated with such a model. The U.N. Charter did not define the concept of the state as the Peace of Westphalia (based on the Treaties of Osnabrück and Münster of 1648) and the Congress of Vienna (1815) had, but it

granted general recognition of the concept to those outside western Europe, an action unprecedented in world politics.

The U.N. cannot simply be called an international organization; it comprises a conglomeration of institutions, nations' domestic priorities, and individual personalities. The U.N. operates under six principal organs: the General Assembly, Security Council, Economic and Social Council, Trusteeship Council (effectively suspended in 1994), International Court of Justice, and Secretariat. These organs oversee twenty-one distinct programs, institutes, and entities. Nothing puts the magnitude of the U.N.'s work in perspective better than the numbers: it has forty thousand employees from all member countries and a budget of \$4.2 billion, excluding peacekeeping operations.

Center of Politics

To accommodate the voices of all member countries but maintain a small body that acts in times of crises, the General Assembly and the Security Council were created in 1945 and remain at the center of U.N. politics. As of mid-2010, 192 nations—all member countries—are represented in the General Assembly, which acts primarily as a deliberative body funneling research and recommendations to other organs of the U.N. The five permanent Security Council members—China, France, the Russian Federation, the United Kingdom, and the United States (i.e., those nations responsible for the defeat of Germany, Italy, and Japan in World War II)—and ten rotating members decide on plans of collective action involving all member countries, with the use of force if necessary, as outlined in Chapter VII of the U.N. Charter.

Illustrated sheet music cover (c. 1900) for “United Nations March and Two Step” depicts five women warriors identified as Russia, France, America, England, and Italy. New York Public Library.

The five permanent members have the controversial veto power to block any proposal brought before the council by casting a negative vote.

While the United States and the former Soviet Union battled for political ground in the Security Council during the Cold War, the General Assembly underwent a rapid transformation because of the influx of new decolonized members during the 1960s and 1970s, with the membership trebling to reach 154 by the end of the 1970s. Previously marginalized issues were given unparalleled legitimacy on the world stage. Concrete results of this paradigm shift include the Universal Declaration of Human Rights in 1948, the establishment of the U.N. High Commissioner for Refugees in 1951, the Freedom from Hunger campaign begun in 1960, the decrease of child mortality rates around the world by 50 percent during the last forty years, and the legal recognition of commercial sea boundaries for all countries in 1994. The promotion of the needs of developing countries during the last half-century—the institutionalized

effect of the U.N.’s global design—is no accident. This agenda is most evident in the eight U.N. Millennium Development Goals, which include achieving poverty, education, health, gender equity, and sustainability targets by 2015.

The U.N. has a mixed record on achieving what the League of Nations never could: the ability to use force to preserve international stability. Whether force is justified, implemented quickly enough, and agreed upon democratically informs much of the criticism and praise given to the U.N. Its successful roles in easing armed conflict in the Congo (1960), El Salvador (1995), and the former Yugoslavia (1999) have been praised, whereas its failures in halting the Soviet invasion of Hungary in 1956 and the more recent Cambodian (1979) and Rwandan (1994) genocides have threatened its credibility. Moreover, we cannot ignore the role that individual national interests play in the cohesion of U.N. member countries. For example, U.S. domestic politics have yielded many unilateral decisions, namely the decision not to initially sign

The United Nations headquarters in New York in 1956, five years after its official opening. John D. Rockefeller donated the \$8.5 million needed to purchase the site, located along the East River. Library of Congress.

the Kyoto Protocol on climate change or to ratify the Convention on the Elimination of All Forms of Discrimination against Women. Most recently the unilateral U.S. interventions in Iraq and Afghanistan have again posed some serious questions about the U.N.'s role and credibility. The U.N.'s ability to work in the interest of all member countries has been routinely challenged.

Reform Needed

U.N. reform is needed in order to evaluate seriously the following questions. How can the imbalance of power between the Security Council, composed of the so-called Great Powers, and the General Assembly be remedied? Should the Security Council be expanded to include powers such as Germany and Japan and rising powers such as India and Brazil? At what point during a civil conflict should nonviolence mean stability and result in the exit of U.N. peacekeepers? Should the U.N. have its own military force and end its reliance on contributor countries for armed

needs? How should national sovereignty be redefined in light of the crimes against humanity committed by a range of governments and the differing international reactions that these regimes received from the international community? How can arms control be made more effective for industrialized and developing countries alike? How should the U.N. work with other transnational associations such as the North Atlantic Treaty Organization (NATO)? Can the U.N. effectively implement results-based budgeting? How will the U.N. fix its infamous bureaucratic backlog and systematic managerial problems? And how is the U.N. best funded in order to allow it to pursue its expanding mandate?

The U.N. continues to be an undeniable force in world affairs. Even when acting in the national interest, the fact that superpowers seek U.N. backing for their actions, as seen in the determination of the administration of U.S. president George W. Bush (served 2001–2009) to receive U.N. sanction for the 2003 Iraq War, demonstrates the continued relevance and legitimacy of the organization. To be

sure, the U.N.'s inability to act in the majority interests of member countries against this war also threatens how future crises will be handled. The ongoing situation in Darfur, Sudan, called "the next Rwanda" by some critics, has proven to be yet another test of the U.N.'s ability to act as an international body working, in the words of its charter, "to save succeeding generations from the scourge of war."

The U.N. has successfully managed to avoid another major international conflict such as a world war, but in respect to its primary aims and objectives, the U.N.'s scorecard for much of its sixty-four years of history reveals a mix of successes and failures. Perhaps the best test of the ongoing significance and importance of the U.N.'s role in maintaining international peace and security is to admit that if it did not exist, something very similar would have to be created from the ground up.

United States of America

The history of the United States is usually taught and written about as if the nation was self-contained, not part of any larger history than itself. Yet history operates across space as well as through time, and the history of the Americas, including the United States, shares world history from its very beginnings.

Because the United States is continental in scale and without threatening neighbors, its history is usually focused inward. The most famous continental interpretation of U.S. history is the frontier thesis of Frederick Jackson Turner, popularized as a story of generations of Europeans moving west. The vision of the United States in Turner's elegant essay of 1893 is deeply embedded in American mythology. Yet Turner was making the point that this westward movement across the continent was coming to an end; the frontier experience would no longer shape American life and values.

Turner offered his larger reflections on modern history and historical method two years earlier when he explained that "we cannot select a stretch of land and say we will limit our study to this land; for local history can only be understood in the light of the history of the world" (quoted in Bender 2006, 12). He was prompted to make this point in the 1890s because global trade and modern means of communications and transportation meant that all nations were, in his phrase, "inextricably connected." A hundred years later, in the 1990s, when talk about "globalization" and the "Internet" became pervasive, the same idea dawned upon historians: perhaps American history should be thought about and taught in terms of its global connections and the history it shares with the rest of the planet.

The world map made in 1459 by Fra Mauro for the King of Portugal shows the ocean encircling the Afro-Eurasia landmass, the known world before the voyages of Columbus.

In fact, the modern history of the Americas and global history commence at the same time. Both are the result of the same rapid sequence of events, from the voyages of Christopher Columbus, Vasco da Gama (who established a sea route from Europe to India), and the expedition captained by Ferdinand Magellan that circumnavigated the globe between 1519 and 1521. Within a quarter of a century of the first recorded Atlantic transit, the planet had been encircled by oceanic voyages. The great achievement of this "age of discovery" was not only the discovery of America but, more importantly, what could fairly be called the discovery of the "oceanic world."

Martin Waldseemüller's 1507 world map was the first to christen the lands of the New World "America," and the first to depict clearly a separate Western Hemisphere with the Pacific as a separate ocean.

This notion requires some explanation. Before the voyage of Columbus maps had shown the ocean as the outer limit of the world, ringing the Afro-Eurasian landmass that was the known world. The Americas were unknown to the peoples of that world, as the Afro-Eurasian world was unknown to the first peoples of the Western Hemisphere. Jews, Christians, and Muslims shared the Old Testament account of the origins of that world. God had pulled back the ocean to make land for the beginning of the human family, Adam and Eve.

The place that Columbus found and began to explore was first labeled "America" by the German mapmaker Martin Waldseemüller in 1507; his map first showed the hemisphere as separate from Asia. The name, which Waldseemüller wrote over what is today's northern Brazil, came from Amerigo Vespucci, a Florentine who had explored the mouth of the Amazon River in 1499. He called the hemisphere *Mundus Novus* or "new world." Educated in the classics, he recognized that the ancients had known nothing of what he saw. But it was new in a different way as well. The ancient Greeks knew that you could sail west from Iberia (Spain) to Asia, except that the ocean was in the way. The discovery that the ocean was not in the way,

that it was in fact the connector of all the continents, transformed understanding of the planet. It extended the world to include the oceans as well as the land of the planet, making history global. Rather quickly the new globality entered the literary imagination. A Spanish scholar and writer in 1540 wrote a fantastic account of a journey to the moon, which included a view of the Earth as a globe, prefiguring by centuries the photographic image of the moon made by U.S. astronauts in 1969. The cities, empires, and nations that would develop from the seventeenth century on would be part of global history; their histories could not be wholly separated from that larger history.

The peoples of the world, including the adventurers who established the first settlements in British North America, were worldlier than we usually assume them to have been. Captain John Smith, who rescued from disaster the Jamestown settlement in Virginia, England's first continental settlement in 1607, is an example. He had seen a good part of the world before he joined the Jamestown project, perhaps somewhat by accident. The usual colonial narrative seems to suggest that his life "abroad" consisted of his few months in Virginia. In fact, that brief experience was embedded in a longer train of experiences in Europe,

Portrait of Captain John Smith from his map of New England. Smith credited his successful intervention in the Jamestown colony to his prior experiences in foreign travel and war.

Central Asia, and Africa that were remarkable but not unique for European adventurers. Smith, who in his teens had gone to the European continent to fight the Catholics, afterward on his return to England met an aristocrat from the former Byzantine Empire. He mentored Smith, making the son of a yeoman into a gentleman. At the age of twenty, he went forth to see the world and to “trie his fortune against the Turks” of the Ottoman Empire, who had recently conquered parts of the Habsburg Empire (Kupperman 2007, 53). He joined the Austrian and Hungarian resistance to the Ottoman armies, learning the art of war, including a command that resulted in the capture of a Hungarian town that had been held by the Ottomans.

His next military adventure, in the service of a Hungarian prince, dragged on in a stalemate, neither side able to mount an effective attack. The Turkish

commander proposed that one Christian soldier compete with him one on one to decide the battle. Smith was selected; he beheaded the leader and two subsequent challengers. The Hungarian prince honored him with a Hungarian coat of arms that displayed three heads. In a subsequent battle he was injured, but villagers rescued him and nursed him to health. Then, however, they then sold him into slavery. The noble who bought Smith gave him to his mistress, who became fond of him. To protect him, she sent him to her brother, an Ottoman military officer stationed in the Black Sea region. The officer turned out to be a cruel master, and Smith rebelled, killing the officer. He then fled to North Africa, where he met the king of Morocco, who was at that time in correspondence with Queen Elizabeth of England proposing a joint colonization project in the Americas. Smith might have gotten the idea of an American adventure there. At any event, he returned to England and joined the Jamestown project. Does all of this travel and fighting make any difference for American history? Smith thought it had. “Warres in Europe, Asia, and Africa taught me to subdue wilde salvages in Virginia and New England, in America.” (Barbour 1986, 269)

In examining the question of America in the world, this essay does not address the foreign relations of the United States. That is another topic. Here the aim is to show the participation of the United States in world history as part of the common history of the world. It makes the point that the history of the United States is, as Turner suggested, a local example of a larger history that may be global in extent. So the question is whether these larger histories help explain the development of the United States. In fact, major events of American history—and many others besides—cannot be adequately explained other than in part by locating them in world history. For examples, the American Revolution, the Civil War, and Progressivism and the beginnings of the modern welfare state will serve here.

The American Revolution

We usually think of the American Revolution as a very specific and local event: resistance by the thirteen

The marriage of Pocahontas, engraving after a painting by Henry Brueckner (c. 1855). Romanticized accounts of Pocahontas's life often overlook her role as a vital link between Native Americans and the British. Library of Congress.

colonies in the face of unwelcome changes in British colonial policies in North America. It was in fact an episode in the “Great War” between England and France. This war lasted episodically for 126 years, from 1689 to 1815, and after 1753 it was a global war, fought on every continent.

The competition between England and France was costly to royal finances. Governments had to show the taxpayers at home that new taxes were worth it, or they had to find other sources of funds, most obviously from the colonies themselves. Historians refer to the financial and governance squeeze as a “military-fiscal crisis.” The British victory in the Seven Years’ War (1756–1763) was so spectacular that it greatly enlarged the empire, at the expense of the French, who lost Canada and trading centers in Africa and Asia. To meet the costs of the war and to secure the new territories, the British crown and Parliament turned to the colonies for new revenue. This decision led to the sequence of infamous (in America) taxes that triggered the resistance that developed into a successful war for independence. But the high cost of empire and imperial wars affected the Portuguese and Spanish empires as well. And they turned to similar strategies. The fiscal crises both faced, as well as new Enlightenment ideas of rational administration, inspired novel imperial policies that promised more revenue.

Any changes in the rules of the game, however, can unsettle established customs and hierarchies of status and power. That happened in all of the empires. Established elites felt that they were being marginalized, that traditional forms of power formerly available to them were being diminished or taken away entirely. They also felt that they were suddenly being treated as second class, when they thought themselves as equal in rights to those in the home country. There were tensions and forms of resistance throughout the Americas, and in the British case expansions of imperial power in India (by way of the East India Company) produced military conflict in the Bengal region of India. There were major eighteenth-century colonial revolts in Colombia and Argentina, and the Portuguese were confronted with a number of smaller plots and rebellions. The rebellion in Peru and the La Plata region of Spanish America in 1782 that was led by Túpac Amaru, descendant of the last Inca king, almost brought down the empire in today’s Peru, Bolivia, Uruguay, and Argentina.

The Thirteen Colonies would not have succeeded in their rebellion without the financial aid, diplomatic support, and military assistance of France. Why did an absolutist monarchy support the American republicans? Because the French had lost badly in the Seven Years’ War, they wanted revenge on Britain. Even the

The British general Cornwallis surrenders to French troops (pictured left) and American troops (seen right), at the Battle of Yorktown in 1781. The American Revolution would not have succeeded without French support.

Marquis de Lafayette, who later became a great friend of the Americans, declared that his initial motive for joining the American cause was simply to battle Britain. It was to damage England rather than to help the Americans that France gave its support.

To understand the American Revolution within the context of the long war between France and England that did not end until 1815 is to revise the chronology as well as the geography of the age of revolution. After the Treaty of Paris (1783), which recognized the independence of the United States, the new nation could not fully exercise control over its territory. Britain still had forts in the Ohio Valley, for example. Nor could the Americans protect their sailors from “impressment,” a form of kidnapping of American sailors by the British for service on their ships. Before the United States could fully exercise its independence, the Great War had to end as it did in 1815, with the defeat of Napoleón by the British.

The intense partisanship in the politics of 1790s and creation of political parties, something not anticipated by the founders or provided for in the Constitution, were also a result of foreign issues, particularly a deep division of opinion about the French Revolution and the wars that followed it. But the first American party system, as political scientists call it, and the passionate political conflict associated with it, dissolved in 1815, when the Great War ended. Historians call

this postparty period the “era of good feelings,” but this change was not the product of a sudden desire to be nice in Washington; rather it was a result of the end of the international irritant.

This wider view also opens the way for understanding the importance for American history of the third great eighteenth-century revolution: the extraordinarily wealthy French slave colony of Saint Domingue, or as it was called after independence, Haiti. Federalists and Jeffersonians divided over whether to aid and support Toussaint Louverture, the former slave who led the revolution. John Adams was supportive, with matériel as well as foodstuffs, while Jefferson embargoed the second republic in the Americas, a black republic. This largest slave revolt in history shook planters throughout the Americas, including Jefferson, who was in a panic. Ironically, it also gave him his greatest accomplishment as president. The loss of Haiti prompted Napoleón to sell Louisiana.

The Civil War

The American Civil War is the moral core of American history. Yet it also invites a global framing as part of the nineteenth-century invention of the modern nation-state and the turn against unfree labor—conditions under which people must work against

I am a firm believer in the people. If given the truth, they can be depended upon to meet any national crises. The great point is to bring them the real facts. • **Abraham Lincoln (1809–1865)**

Photo by Alexander Gardner.

their will, including slavery, debt bondage, serfdom, or prison labor—in the Atlantic world. The immediate transnational context was the European revolutions of 1848. Abraham Lincoln, who had been elected to the U.S. House of Representatives in 1846, admired the European liberals who were seeking to transform monarchies into parliamentary nation-states. These liberals, as well as Lincoln and the Republican Party, linked nation and freedom, with the nation a vehicle for achieving greater freedom.

Lincoln also absorbed their redefinition of the meaning of national territory, particularly the demand for homogeneity within national borders. In central Europe homogeneity meant linguistic or ethnic homogeneity, but that was not the meaning for Lincoln. He had strongly opposed the anti-immigrant Know Nothing Party of the 1850s; for him homogeneity meant the nation would be all free or all slave. That was the

underlying logic and conclusion of the famous “House Divided” speech he delivered in 1858. Of course, the nation had been divided from the beginning. It was a political problem to be compromised, as it was in the 3/5 clause of the Constitution and in subsequent compromises, such as the Missouri Compromise that established a line equally dividing slave and free territories. The new Atlantic-wide understanding of the nation-state made such compromise impossible. The passion of Lincoln and those who supported the Republican Party in 1860 cannot be understood without awareness of this new understanding of the nation that was circulating around the globe.

The United States was also experiencing a federative crisis, arguing over the relation of national and local power. The Republicans were strong nationalizers, while southern politicians embraced decentralization that would allow individual states to protect their “peculiar institution.” This struggle between centralization and decentralization was a global phenomenon, and wars were fought in Europe (Germany and Italy) and Latin America, particularly in Argentina, but also Brazil and Chile. The issue was resolved without war in Japan, with the Meiji Restoration, and in Siam, today’s Thailand, where a modern state structure was established under the leadership of the monarch. Although the nationalist revolution in Hungary against the Habsburg Empire failed in 1848, Hungary achieved self rule in domestic matters in 1867, under what became the Austro-Hungarian “Dual Monarchy.” There were also efforts to strengthen the Russian and Ottoman empires, making them more like modern European states. Equally important, emancipation, or freedom, was part of the process of nation making in the middle of the nineteenth century. While the United States freed four million slaves, another forty million serfs were emancipated in the Habsburg, Russian, and other empires.

Not only did Americans feel themselves part of the liberal movements of 1848, a point made repeatedly by Lincoln—and by common soldiers as well—but the great European liberals, from John Stuart Mill in England to Giuseppe Garibaldi in Italy to Louis Kossuth in Hungary, also understood the American Civil

This World War I propaganda poster, designed to appeal to the United States' large immigrant population, was printed in many different languages. Library of Congress.

War to be a crucial episode in the history of liberal reform well beyond the United States.

Progressive Reform and the Welfare State

American progressivism was part of a broad transformation of laissez faire liberalism into what was called variously the new liberalism, economic liberalism, or social liberalism. Its beginnings in the United States were in the 1890s and it culminated in the American welfare state in the 1930s established by Franklin D. Roosevelt's New Deal. This movement was part of a global response to massive urbanization and industrialization under conditions of unregulated capitalism. A global menu of reform ideas was available to all industrializing nations. Many of the key ideas originated in the economics

The embrace of 2nd Lt. William Robertson and Lt. Alexander Sylvashko symbolizes the historic meeting of the Russian and American armies, near Torgau, Germany, on 25 April 1945. National Archives.

seminars of German universities; these ideas were particularly important in the United States and Japan. But there was a general circulation of ideas; all industrial nations were borrowing ideas from each other.

Somewhat counter-intuitively, reformers realized that modern urban and industrial society held more daily life risks than did the agricultural era. Modern society is a risk society, no safer than a jungle, and it required novel forms of protection. This was pointed out in the very title of the reform novel published by Upton Sinclair in 1906: although set in a city, Chicago, the title was *The Jungle*. Risk is best addressed by insurance, and what became the twentieth-century welfare state was a combination of regulation and social insurance.

All urban and industrial nations developed programs of insurance against old age, industrial accidents, illness and injury, and unemployment. If the ideas were in general circulation, the policy outcomes were distinct. While other industrial nations included health insurance in the social liberalism package, the United States did not. On the other hand, the United States moved very fast to protect pure food and drugs, beginning with milk inspection in the 1870s in New York City.

Here is where one must be careful, however. If the policy ideas and examples were available to all, the politics of reform had national distinctions. Why? Local cultural and political traditions, national politics, the balance of interests produced different versions of the new liberalism. For example, opposition

The “Colonial Tree,” with its roots in Old World soil, has a branch for each of the thirteen colonies—plus one that commemorates the “failures” of early settlements.

to the reforms came from different groups in different nations: in Latin America and Russia it was the landed classes; in the United States and Japan it was big business. This is why a national history in a global context is not global history. It is both global and national, but in the end the point is to explain a national history.

By examining the history of the United States in the larger context of world history, national history is not dissolved but rather its distinctiveness becomes clearer. But the global context also provides fuller explanations of how change has happened, and it becomes easier to understand why U.S. history differs from other histories as well as to better understand how much is shared.

It is often claimed that American history is exceptional; placing American history in a global context undermines this exceptionalist notion of American history. Yet the specific distinctive aspects of the history of the United States, those that make it a unique

nation, are clarified and accented. The problem with an exceptionalist interpretation of American history is that it presumes a norm, or a rule, that has one exception, the United States. That implies that the United States does not share a history with other nations, thus putting the United States outside of the common history of humankind, which obviously is not the case. There is a second problem with the argument for exceptionalism. The claim of exceptionalism requires a norm followed by everyone else. But there is in fact no norm. A global perspective reveals a spectrum of unique resolutions of many common or even universal challenges. A global perspective reveals that the United States is unique but not exceptional.

Universe, Origins of

Origin stories of all cultures face one fundamental question: how can something come from nothing? They then attempt to explain the complexity of our universe: which things came first, which came later? But unlike stories of myth, the modern theory of the origins of everything—the big bang—rests on a colossal body of carefully tested information and is powerful enough to have achieved the respect of scientists throughout the world.

In all cultures that we know of, accounts of the histories of particular communities are embedded in accounts of the history of landscapes, animals, the Earth, the stars, and the universe as a whole. All cultures understand that history begins with the origins of the universe. To understand what we are and where we have come from, we need to understand the history of the entire universe. Cosmologies offer the largest possible framework within which to think about our place in time and space.

Traditional Origin Stories

On the surface, origin stories often seem utterly different from each other. But all are attempts to grapple with the same fundamental questions. At the very beginning, they have to explain how something can come out of nothing. Some origin stories (including the Genesis story) claim that a god or gods created the universe and ignore the nagging question of how the gods were created. Many origin stories begin with a sort of nothingness out of which something appears without any clear explanation of how and why. In this way they confront the most basic duality of all:

between nothing and something. Many origin stories posit an initial state of chaos that is not quite existence and not quite nonexistence; then, out of this state arise both existence and nonexistence. Often, this mysterious process is compared to sexual reproduction, another strange form of creation in which the coming together of two people creates a third person. Robert Graves, a British author and poet renowned for his writings on mythology, summarizes an ancient Greek myth in which chaos is at the beginning, and is in some sense the creator and ground of reality. The following excerpt from Barbara Sproul's book *Primal Myths* illustrates how origin stories use richly symbolic narratives to deal with problems that still challenge us today.

In the beginning, Eurynome, the Goddess of All Things, rose naked from Chaos, but found nothing substantial for her feet to rest upon, and therefore divided the sea from the sky, dancing lonely upon its waves. She danced towards the south, and the wind set in motion behind her seemed something new and apart with which to begin a work of creation. Wheeling about, she caught hold of this north wind, rubbed it between her hands, and behold! The great serpent Ophion. Eurynome danced to warm herself, wildly and more wildly, until Ophion, grown lustful, coiled about those divine limbs and was moved to couple with her. Now, the North Wind, who is also called Boreas, fertilizes: which is why mares often turn their hind-quarters to the wind and breed foals without aid of a stallion. So Eurynome was likewise got with child. Next she assumed the form of a dove, brooding on the waves and in due process of time, laid the Universal Egg. At her bidding, Ophion coiled seven times about this egg, until it hatched and split in two. Out tumbled all the things that exist, her children:

sun, moon, planets, stars, the Earth with its mountains and rivers, its trees, herbs and living creatures. (Sproul 1991, 157)

As this story suggests, once they have explained the origins of the universe, origin stories face many other complex questions. Can they explain the great variety and complexity of our universe? Which things came first, and which came later? Was there always conflict between different parts of the universe, or was the universe once a place of harmony? A Californian creation myth from the Cupeno tribe offers its own symbolic answers to these questions: “In the Beginning all was dark and void. A bag hung in space. In time it opened out into two halves. From one half came coyote (*isil*), from the other came wild cat (*tukut*). They immediately fell to arguing as to which was older” (Sproul 1991, 242). Primeval chaos, gods, fertilized eggs, sexuality, and a primordial division into two—these elements weave their way through many traditional creation myths.

Early Scientific Theories

Modern scientific origin stories face the same questions and paradoxes, but they try to deal with them without supposing the existence of gods or even of intentionality. Can the origins of everything be explained purely by the operation of blind natural laws? The question remains open even today for, despite the spectacular achievements of modern cosmology, we still don’t know how best to explain the moment of the universe’s origin. The origin myths of medieval Europe, from which modern cosmology evolved, described how God created a universe whose shape and movements could be described rationally within the cosmological models of the Egyptian astronomer Ptolemy (second century CE). In Ptolemy’s system, the Earth lay at the center of the universe, surrounded by a series of transparent, revolving spheres to which were attached the planets, the sun, and the stars. Ptolemy’s model worked extremely well for a long time, and proved quite accurate at predicting astronomical phenomena such as the movements of planets and stars. In

sixteenth- and seventeenth-century Europe, however, other models supplanted it. The Polish astronomer Nicolaus Copernicus (1473–1533) argued that the Earth and planets revolved around the sun, while the Italian philosopher Giordano Bruno (1548–1600) argued that many of the stars were themselves suns, each perhaps with its own solar system. The new models generated during the early years of modern astronomy envisaged a universe much larger than Ptolemy’s, in which the place of the Earth and human beings became increasingly insignificant. By the end of the seventeenth century, many accepted that the universe might be both eternal and infinite.

An Expanding Universe

The idea of an eternal universe created new problems. The astronomer Johannes Kepler (1571–1630) pointed out that in an infinite universe there ought to be an infinite number of stars and an infinite amount of light pouring down on the Earth both by day and by night. The development of the theory of thermodynamics in the nineteenth century suggested another problem: in an infinitely old universe all useful energy ought to have dissipated into heat, leaving no free energy to create or sustain complex objects such as stars, planets, and living beings.

The one who walks the way of truth creates life. • Sumerian Proverb

Solutions to these problems, along with a new view of the universe itself, emerged early in the twentieth century. Studies of the structure of the universe revealed, first, that it consisted of many galaxies, not just the Milky Way, for many remote objects turned out to be galaxies in their own right. Then, in the late 1920s, Edwin Hubble (1889–1953) used the Mount Wilson telescope outside of Los Angeles to show that most distant galaxies seemed to be moving away from Earth-bound observers. Technically, he found that the light from distant galaxies was “red-shifted,” or moved to lower frequencies, which seemed to be the result of a Doppler shift. (The same effect accounts for the drop in pitch of a siren as an ambulance moves away from us.) Even more astonishingly, he found that the farther away they were, the more “red-shifted” their light was, and the faster they seemed to be moving away from the Earth. Assuming that the Earth’s position in the universe is not in any way special, so that observers elsewhere in the universe must be seeing the same thing, Hubble concluded that the entire universe must be expanding. If it was expanding now, it followed that it must have been smaller in the past, and that at some time in the past, it must have been infinitely small. Hubble’s observations might have seemed little more than a curiosity if it had not been for the fact that Albert Einstein (1879–1955), in his General Theory of Relativity (1916), had also posited that the universe might be either expanding or contracting. At first, Einstein resisted this conclusion, but by the late 1920s, he had been persuaded by the work of a young Russian mathematician, Alexander Friedmann (1888–1925) that the universe, like a pin standing on end, was unlikely to be entirely stable. In reality, it was much more likely to be either expanding or contracting, and Hubble’s evidence suggested it was expanding.

Big Bang Theory

Despite both observational and theoretical findings, the idea of an expanding universe remained little more than an intriguing hypothesis until after World

War II. Theorists such as the Russian-American physicist and astronomer Arthur Gamow (1904–1968) and the British astronomer Fred Hoyle (1915–2001) worked on the implications of an expanding universe and found that it was possible to construct a surprisingly coherent picture of how matter might have behaved under the extreme heat and pressure at the very beginning of the universe’s history. Nevertheless, for a time, the big bang theory had to compete with an alternative theory, the so-called steady state theory, developed by Hoyle and others in the 1950s. (Indeed, it was Hoyle, one of the fiercest critics of the big bang theory, who coined the phrase “big bang,” in a lecture in 1950.) In an attempt to preserve the idea of an eternal, and essentially unchanging, universe, the steady state theory suggested that matter was continually being created throughout the universe at just the rate needed to counteract the apparent rate of expansion. The steady state theory implied that the universe had always been much as it is today, a hypothesis that was soon tested. By the early 1960s, improvements in radio astronomy enabled astronomers to make more careful studies of remote galaxies. Because light takes a finite time to travel, such studies were, in effect, examining the universe in its youth, and what soon became apparent was that the early universe was very different from the universe of today. Clearly, the universe had changed over time, as the big bang theory implied.

Even more important was the discovery, in 1965, of cosmic background radiation, by two American scientists, Arno Penzias (b. 1933) and Robert Wilson (b. 1936). In trying to construct an extremely sensitive radio antenna, they found a persistent hum of weak energy coming from all directions in space. Energy coming from a particular place in space made sense, but they could imagine no force that could generate energy from all parts of the universe, until someone told them that this was exactly what the big bang theory predicted. Attempts to model the early history of the universe had suggested that as the universe cooled there would come a point when protons and electrons could combine to form atoms. Atoms,

A composite image of the Eagle Nebula (M16) from NASA's Chandra X-ray Observatory and the Hubble Space Telescope penetrates dark columns of gas and dust: star formation peaked in this region several million years ago.

unlike naked protons and electrons, are electrically neutral, so as atoms formed most of the matter in the universe lost its electric charge. At that point, matter and energy would in effect become disentangled, and energy would be free for the first time to travel at will through the universe. Early big bang theorists had suggested that this sudden release of energy ought to be observable even today, and it was soon clear that this was exactly what Penzias and Wilson had detected. The steady state theory had no explanation for cosmic background radiation, but the big bang theory seemed to explain it naturally. The discovery of cosmic background radiation was a knockout blow to the steady state theory; ever since, the big bang theory has provided the core idea, or paradigm, of modern cosmology.

Big Bang Cosmology

Working out the details of big bang cosmology remains a complex task, but no other theory comes close to explaining as much, so few cosmologists doubt that it is essentially right, even if some of its details may need to be modified in the future. One

reason for this confidence is that new evidence for the theory has emerged since the 1960s. As the power of telescopes has increased, astronomers have found that the most remote parts of the universe are indeed very different from those closest to us, and those differences fit very well with what big bang cosmology suggests about the nature of the early universe. Measurements of the age of materials in the solar system have also failed to come up with anything more than about 13 billion years old, which corresponds to the most recent estimates of the age of the universe. Furthermore, big bang theories suggest that most of the matter in the early universe would have consisted of hydrogen and helium, with other elements being created within stars or in the violent explosions of giant stars known as supernovae. This is consistent with what we observe: almost three-quarters of all atoms are hydrogen, almost one-quarter are helium, and the rest include all other elements.

In its general outlines, the origin story of big bang cosmology is simple, even though many of its details are too complex to be understood by any but physicists and cosmologists. The most recent estimates of the speed of expansion of the universe suggest that the universe appeared about 13.7 billion years ago. Before that time we have no idea what there was. We don't even know if time and space existed, and the conventional wisdom is that they, along with energy and matter, were probably created at the moment of the big bang. We also have no idea why the big bang occurred when it did. Modern science is as powerless as traditional creation stories to explain the moment of origin. But from a tiny fraction of a second after the appearance of the universe we can describe what happened with great precision. Something appeared within the primordial emptiness. This early universe was almost infinitely small, and almost infinitely hot. At temperatures of billions of degrees, time, space, energy, and matter would hardly have been distinguishable. The pressure of this concentrated energy drove the early universe apart; indeed, for a moment within the first second of its existence, the universe expanded faster than the speed of light. From the

size of an atom it blew up to many times the size of our solar system. Soon after this phase of rapid expansion (known as “inflation”), particles of matter and antimatter collided and annihilated each other, leaving a huge amount of energy and a tiny residue of matter. As the universe expanded, it cooled, and as it cooled different forms of energy and matter separated out from the initial flux. Gravity appeared, then electromagnetism, together with the strong and weak forces that shape the behavior of atomic nuclei. Quarks appeared and, within two or three minutes, the first protons and electrons.

For almost 400,000 years, the universe was still too hot for protons and electrons to combine into atoms, so that the entire universe crackled with electrical energy. Then, about 380,000 years after the big bang, the universe cooled sufficiently for protons and electrons to come together to form the first atoms, of hydrogen and helium. Matter became electrically neutral, and energy and matter went their separate ways, releasing the flash of energy that is detected today as cosmic background radiation. The next significant event occurred some 200 million years after the big bang, when clouds of hydrogen and helium began to collapse, drawn together by gravity, until their centers heated up to about 10 million C. At that point hydrogen atoms started fusing to form helium atoms, releasing a colossal amount of energy in the process (in nuclear reactions identical to those within a hydrogen bomb). The first stars were born. The release of energy at the center of a star checks the gravitational collapse of the cloud of matter from which it is formed and creates a more or less stable structure that can pump out huge amounts of energy for billions of years. Stars play a vital role within the modern creation story because they supply the energy that sustains life on Earth. Furthermore, in their dying stages some of them, particularly the very largest, can generate temperatures high enough to fuse nuclei together into more and more complicated elements. When the very largest stars die in violent explosions known as supernovae, all the remaining elements of the periodic table are created. It is from these elements that newer and more complex structures, such as planets and living organisms, can

eventually be constructed, using the energy of gravity and the heat energy pouring out of stars.

Is this story true? It is by far the best story available at present, but it is far from complete. Cosmologists wrestle with the problem of the very earliest moments, frustrated that they seem to have no way of even testing hypotheses about the moment of origin. And even the tiny fraction of a second after the beginning of the universe presents some complex puzzles. Above all, physicists and cosmologists wrestle with the problem of the relationship between gravity and the other fundamental forces of modern physics. The relationship between electromagnetism and the “strong” and “weak” nuclear forces is now largely understood, but how gravity fits in remains unclear. New observational techniques (including the use of satellite-based observatories) and new computational techniques have generated a mass of new data about the early universe, and some of this torrent of new information has forced cosmologists to rethink parts of the story. In the late 1990s, for example, evidence from the study of very remote galaxies showed that the rate of expansion of the universe is not slowing under the gravitational pull of the matter in the universe, as most cosmologists had assumed. On the contrary, it is speeding up. What this means remains uncertain, though most cosmologists believe it may be evidence for the existence of an anti-gravitational force that had already been anticipated in some of Einstein’s work. Even more disturbing is the slow realization, from studies of the movement of galaxies, that there exists a lot more “stuff” out there than we can detect. Currently, it seems likely that the matter we can observe accounts for no more than about 5 percent of the mass of the universe, while some 25 percent of its mass probably consists of matter (known, appropriately, as “dark matter”) that we cannot yet detect or explain, and perhaps as much as 70 percent is accounted for by forms of energy (known as “dark energy”) that we cannot yet detect or fully explain. To be uncertain about almost 95 percent of the contents of the universe is a serious embarrassment to modern cosmology.

Like traditional creation stories, the modern account of the origins of the universe remains a work in progress.

But unlike those stories, the modern story of the origins of everything rests on a colossal body of carefully tested information and is powerful enough to have achieved the respect of scientists not just within a single culture, but throughout the world. It is the first account of the origins of the universe to have achieved near universal respect.

Universities

Popes, emperors, and kings chartered the first universities in twelfth-century Europe; teachers recruited students and taught Christian doctrine through lecture, debate, and reasoning. After the Renaissance, the curricula became secularized and specialized encouraging independent thought and research. European colonialism spread the university system around the world, and countries retained and modified the systems after their independence.

Universities originated in medieval Europe when groups of teachers and students attained special privileges and a corporate identity through charters from popes, emperors, and kings. University students and teachers governed themselves, electing rectors and other officers to manage their affairs. Teachers charged students a fee for attending their lectures, and over time pious donors financed special college buildings where students and faculty lived and ate. Classrooms and libraries later supplemented the earliest buildings. Books were still rare and expensive in Europe at that time, and unavailable to ordinary people, so oral presentation and argument prevailed.

Christianity and Universities

The University of Paris, founded between 1150 and 1170, specialized in trying to untangle Christian doctrine. The university took direction from the work of a famous teacher named Peter Abelard (1079–?1142), and it became a model for other European universities. Abelard was decisive in establishing the idea that apparent contradictions in the Bible and among the early Christian fathers could only be resolved by

logical reasoning. He compiled a book of quotations from sacred and revered Christian texts, titled *Sic et non* (Yes and No), setting conflicting views side by side so no one could doubt that there were important questions to be answered. *Organon*, a work of the third-century-BCE Greek philosopher Aristotle, was already available in Latin translation; it offered Abelard and those who followed him a convenient tool to try to resolve such differences by logical reasoning.

Translation of the rest of Aristotle's writings in the thirteenth century CE enlarged the impact of his philosophy among Parisian teachers, leading them to supplement theology with the study of physics and other subjects Aristotle had written about. But arguments about Christian doctrine remained central. When books became more accessible, a teacher in Paris named Thomas Aquinas (1225–1274) published a book titled *Summa theologiae*, which gives his answers to most of the questions that centuries of debate had raised. It eventually became the official and authoritative repository of Catholic teaching, although Aquinas's views were disputed in his own day, and in 1277, soon after he died, some of them were formally condemned as heretical by teachers of the University of Paris.

Rise of Secularism and Specialization

Disputation and new views on theological and other questions were encouraged within European universities by competition among professors, whose income depended on how many students they attracted. Challenging established ideas was a good way to gain their attention, and doing so kept debate alive for generations, even when popes, rulers, and elderly professors

An old engraving of the grand portal and church of the Sorbonne, part of the University of Paris.

tried to impose uniformity and agreement. Since translations of Aristotle's writings were soon supplemented by the discovery of other pagan texts—literary, historical, as well as philosophical—and since new information about the rest of the contemporary world kept pouring into European cities, the subject matter of university teaching kept expanding as well.

To be sure, there were ups and downs in the intellectual vigor of every university, and many important intellectual developments took place outside their classrooms. Self-styled “humanists” of the Renaissance (mid-fourteenth through seventeenth centuries), for example, seldom worked in universities where sacred texts took precedence; it took a long time for classical literary studies to get access to university lecture halls. Then the Reformation and Counter-Reformation (both in the sixteenth century) imposed a Protestant or Catholic identity after 1517 on every European university, whereupon angry defense of rival doctrines embittered and narrowed university education. Consequently, early modern science flourished mainly within new institutions like the Royal Society of England, founded in 1660, though the English physicist and mathematician Sir Isaac Newton (1642–1727) was a professor at Cambridge University for most of his life. Later, in the eighteenth century, the French

Enlightenment, which consciously repudiated Christianity, arose among a circle of literary men. But in Germany, universities played an active part in the parallel secularization of thought without ceasing to train Protestant and Catholic clergymen.

This dual role was due to the fact that German university education assumed new forms after Frederick III, Elector of Brandenburg, founded the University of Halle in 1694. Its professors abandoned Latin and started to lecture in German. They taught students to seek private contact with God through prayer and to disregard old arguments about theological doctrine. Instead they prepared students for careers as government officials, largely by the study of classical Greek and Roman texts. In short, personal piety supplanted theological disputes, and secular themes and ideas engaged more attention, while geographical exploration and scientific discoveries kept on supplying new information that had to be fitted into older ideas somehow. A generation later, another new university at Göttingen (1737) followed a similar path, broadening emphasis on science and statistics. Other German universities gradually did likewise, capped by the establishment of the University of Berlin in 1809, which became a model not just for Europe but for much of the world across the next century.

Everywhere I go, I'm asked if I think the universities stifle writers. My opinion is that they don't stifle enough of them. There's many a best seller that could have been prevented by a good teacher. • **Flannery O'Connor (1925–1964)**

As Abelard had set the tone and agenda for the University of Paris in the twelfth century, Wilhelm von Humboldt (1767–1835), then serving as minister of education for the Kingdom of Prussia, and himself a student of Basque and other obscure languages, made research and the discovery of new truths the central task for professors at the University of Berlin. They were expected to share their discoveries with undergraduates through lectures, and also to offer seminars to graduate students, showing them how to do specialized research. Within a decade Georg Wilhelm Hegel (1770–1831) was teaching his own personal philosophy at Berlin. It became in effect a substitute for Christianity among his followers. His example provoked other German philosophers to disagree with him, much as the teacher at Paris had disagreed about theological questions centuries before.

Natural sciences, linguistics, history, philology, and Christian theology (soon subjected to the so-called higher criticism) all had their place in Humboldt's university alongside secular philosophy. Specialization prevailed. Each professor and student and each separate discipline was free to go its own way. This, and the notion that teachers ought to prove themselves by doing research and discovering new truths, proved infectious, not only within Europe but in much of the rest of the world, so that in the twenty-first century, thousands of universities aspiring to expand as well as transmit knowledge exist in most countries of the world.

University Education around the World

France and Great Britain had different educational traditions and implanted second-rate replicas of their universities in most of their colonial possessions during the nineteenth and early twentieth centuries. At home they disregarded the German ideal of university-based research at first. They embraced it with variations only after the 1880s, and so did the United States. But Adolf Hitler's Third Reich (1933–1945) demoralized German universities; in the twenty-first century, university-based research, as pioneered

in Germany and subsequently paralleled in the United States, France, Britain, and Japan, does much to shape contemporary science and other disciplines.

Modern universities have also arisen elsewhere, even though each of the world's civilizations had its own established forms of higher education. All of them sought changeless religious truth; yet despite that hope, all adjusted teaching across time to take account of new information and new conditions of society. Europeans did the same, as this article has suggested. But when Europe's wealth, power, and prestige surged suddenly after 1750, due to the Industrial Revolution and associated changes in technology and society, the impact of newly expanded and secularized European practices on older, religiously shaped educational traditions was often disruptive.

Indian higher education was radically Westernized by the English after 1834 when the writer and politician Thomas Macauley organized a new system of education conducted in English and designed along liberal lines. Independent India after World War II made no changes, since its leaders had been schooled to take Western ideas and even the use of the English for granted. In China, age-old Confucianism was officially abandoned in 1905, whereupon European missionary colleges and Chinese-managed universities both began to propagate Western learning. When Communists took power in 1949, efforts to enforce Marxist orthodoxy prevailed until 1976, when new leaders opened the country to the outside world with spectacular economic results and allowed teachers and students limited but widening freedom to study Western learning, with special emphasis on natural science.

Among Muslims, resistance was greater, even though the collapse of the Ottoman Empire in 1918 brought a vehemently secular regime to power in Turkey that imported German professors to create European-style universities. But traditional religious teaching survived in Arab lands and beyond. Even though European administrators after 1920 protected Christian missionary universities in Beirut and Cairo, Western learning had slight impact on most Muslims. When the Arab lands achieved full

independence from European control before and after World War II, resistance to European forms of higher education intensified. Ironically, armies and military schools thereafter became the main bearers of European secular and scientific learning in most Muslim states.

Elsewhere the withdrawal of European empires from Africa and Southeast Asia left recently founded colonial universities behind, and local rulers almost always allowed them to persist. In Latin America, universities date back to the sixteenth century; independence from Spain and Portugal, when it came after 1807, did not change these countries' initial Catholic identity. Since then, most Latin American universities have remained marginal within their own countries and little known abroad.

Everywhere, the fundamental issue remains unresolved between those who seek revealed, unchanging, and authoritative truth and those who are content with what human reason can achieve in the way of truths that are subject to revision whenever new evidence or insights may arise. The question is unlikely ever to disappear. The enlarged scope universities gave to human reason from their inception in medieval Europe was exceptional then, and it remains precarious because so many anxious human beings still desperately seek certainty and salvation. Doubtless they always will. And patterns of higher education will continue to differ among

human societies and change over time, just as they have done hitherto.

Urban II

(c. 1035–1099)

ROMAN CATHOLIC POPE AND REFORMER

Pope Urban II was a French-born church reformer and summoner of the First Crusade that recaptured Jerusalem in 1099. He is considered to be one of the most influential popes—in the history of the Roman Catholic Church and in European history as well.

Otho of Lagery (also known as Otto, Odo, or Eudes), who would later become Pope Urban II, was born in France in 1035. He studied at Reims under Bruno of Hartenfaust, who would later found the Carthusian Order and be canonized as St. Bruno. After retirement at Cluny, Otho was sent to Rome to aid Pope Gregory VII in his efforts to reform the church and eventually became the pope's chief adviser. During his years in various church positions, Otho filled numerous vacant church offices with clerics faithful to Pope Gregory VII and removed those whom the pontiff had condemned. Otho became one of the most prominent and active supporters of the Gregorian reforms, especially during his term as legate in Germany. Otho was also among the select few whom Gregory VII had previously nominated as possible successors.

At a conference of Gregorian bishops at Terracina in 1088, Otho was elected pope to replace the recently deceased Victor III. After his election, Otho chose the papal name of Urban II. From the outset of his papacy, Urban II adhered to the reform efforts of Gregory VII and publicly declared his intention of following the policies set forth by his predecessor. In the same manner as his mentor, Gregory VII, Urban II was met with a storm of opposition. He was opposed

not only by laymen but by the clergy, especially by the bishops. The pope would also have been distracted by battles against the Holy Roman Emperor Henry IV and his imperial pope Clement III over whether the imperial or the papal power was to be supreme in Christian Europe. Still in the midst of the Investiture Controversy, Urban II was unable to enter Rome until 1093 due to the presence of the antipope Clement III (Guibert of Ravenna) and the actions of the Holy Roman Emperor Henry IV.

Urban II utilized the conciliar method of church leadership, holding significant councils at Piacenza (1095), Clermont (1095), Rome (1097), Bari (1098), and Rome (1099). At Piacenza the pope approached the subject of the Crusades, after receiving a request for assistance from the Eastern Emperor, Alexius I. The more important council was that at Clermont, where Urban II began by reiterating the decrees of Gregory VII against simony, investiture, and clerical marriage. The matter of Constantinople and Jerusalem was also discussed, and a decision was made to send an army to rescue Jerusalem and the Catholic churches in the East from the Muslim Turks. In his sermon at Clermont, Urban II concluded his remarks with the phrase "*Deus vult!*" (God wills it!). This slogan would later become the battle cry of the crusader.

Urban II's initiation of the crusade movement is significant in world history. The various crusades provided the mechanisms for reopening the trade routes that united the civilizations of Europe and the East. Through these routes many things flowed: paper, the compass, medicines, spices, crops, cultural advances, and gunpowder. The First Crusade

was successful in that Jerusalem fell to the crusaders in 1099. Urban II died on 29 July 1099, fourteen days after the recapture of Jerusalem by the Christian crusaders. Ironically, the pope's death occurred before news of the event had reached Italy.

Although the First Crusade was a military success, some of the consequences were not anticipated by the Byzantine emperor, Alexus I. Instead of restoring Byzantine territories to eastern Catholic rule, the Roman Catholic conquerors established four independent Latin kingdoms. In addition, the Hospitallers, Templars, and Teutonic Knights came into power as religious military orders, with the stated purpose of protecting the pilgrims and holy sites.

The remains of Urban II were interred in the crypt of St. Peter's, close to the tomb of Adrian I. Clearly, without the efforts of Urban II, most of the Gregorian

reforms would not have succeeded. Urban II was beatified by Pope Leo XIII in 1881.

Urbanization

The term *urbanization* describes how cities—from as long as 5,000 years ago and in widely separated regions—grew in number, and how their populations increased and become dense. Growing cities stimulated changes that fostered new migrations and diffusions—and ever more cities.

Urbanization is a process of population concentration. It involves not merely the increasing numbers, size, and density of urban settlements; it is the source of the new opportunities, attitudes, and lifestyles that transform entire societies as they diffuse to smaller places and rural regions and stimulate the streams of migration that produce further rounds of urban growth. Thus urbanization is the vital engine of economic development and cultural change.

Classical Beginnings

Urbanization had several independent beginnings. Primary urban generation occurred in a number of areas widely separated in both time and space: lower Mesopotamia at least 5,000 years ago, the Indus valley 4,500 years ago, the North China plain at least 3,000 years ago, Mesoamerica more than 2,500 years ago, the central Andes and Peruvian coast 2,000 years ago (although recent evidence places the age of the pyramids at Caral at 4,600 years), and the Yoruba territories in West Africa and incipiently in Zimbabwe 500 years ago. Diffusion from already-urbanized societies also stimulated the rise of cities in a number of other areas: Korea and Japan, the Indian Deccan, southwest Asia and the eastern Mediterranean, and the western Mediterranean and Europe. Whether

or not the megalithic complexes of Atlantic Europe served as population concentration nuclei or were freestanding ceremonial sites four and five millennia ago is still a matter of debate.

The characteristic sequence of cultural evolution began with domestication of plants and animals and the emergence of class-based societies, followed by the formation of military and religious elites who gathered clans into states and used their power to extract surpluses from village agriculturalists. In such states there developed hierarchies of specialized institutions that exercised authority over territory and maintained order within their populations. At the core of these states were monumental complexes, the focal points around which capital cities evolved and the *axes mundi* at which leaders could maintain contact with the gods. Frequently, both the ceremonial complexes and the cities that surrounded them were designed as miniatures of the cosmos, in which the appropriate rituals could be performed to ensure that stability and harmony prevailed. Astronomy thus was important not merely for timekeeping and the regulation of the rhythms of agriculture; it was central to the physical plans. The social geography of the cities was predominantly centripetal: the higher the status, the closer a resident lived to the center, but the urban fabric also contained walled “quarters” that separated tribe and clan. The specialists who first emerged as temple and palace functionaries later evolved into producers for the market. Similarly, the merchants who conducted long-distance trade evolved from the networks of tribute that had been secured by military action.

Most classical capital cities were small and compact, yet they were many times greater than other settlements in their domains. Levels of urbanization—the

percentage of the population living in urban areas—never exceeded 10 percent. Secondary centers were few and small and the bulk of the urban population clustered in the capital city. This pattern of capital city primacy prevailed until very recently. Only three hundred years ago there were probably no more than fourteen cities in the world with populations exceeding 200,000 (in imperial China, Beijing 650,000, Hangzhou 300,000, Guangzhou 200,000; in feudal Japan, Tokyo [earlier Edo or Yedo] 680,000, Osaka 380,000, and Kyoto 350,000; in the Moghul Empire, Ahmadabad 380,000 and Aurangabad 200,000; in Iran [then Persia], Esfahan 350,000; in the Ottoman Empire, Istanbul [then Constantinople] 700,000; and in Europe, London and Paris both over 500,000 and Amsterdam and Naples both just over 200,000). No more than fifty other cities exceeded 50,000.

Despite their small size, however, each of these capital cities served as the focus of its own “world economy,” an economically autonomous section of the planet able to provide for most of its own needs. Such economies comprised an immediate *core region* that provided foodstuffs and within which modification of the earth was greatest, a modestly developed *middle zone* controlled by the projection of the capital city’s military power and exploited for transportable resources and products, and a vast and relatively

untouched *periphery* that ensured separation from other worlds, except where long-distance merchants made contact at trading centers located where the peripheries touched.

The First Break

The first break with classical urban patterns that raised the level of urbanization above 10 percent came in the Low Countries of Europe in the seventeenth century. Exploiting new maritime technology—deep-bellied cargo vessels that significantly changed seagoing goods-carrying capacity and costs—a mercantile center, Amsterdam, became the warehouse of the world. In the United Provinces, the middle zone of what later became the Netherlands, urbanization levels rose to more than 30 percent, and a high degree of market-based specialization in cash crops developed for urban consumers and industrial markets. The closer to Amsterdam, greater was the degree of cash-crop specialization and greater the extent of environmental modification. The further from the United Provinces, the more likely it was that regions were still composed of self-sustaining feudal villages. As urban demands increased, ingenious methods of crop rotation were developed to raise productivity and new technologies enabled cultivable polders to be

Underground railroads, or subways, have proven to be an efficient means of transportation in crowded cities. This diagram is a cross-section of the Chicago subway system in the early twentieth century.

created by draining swampland. As important, a new spirit of middle-class Protestantism linked to capitalism was fostered, carrying with it ideas of humans' dominion over nature and the godliness of engaging in production and trade for profit.

The Second Break

Change in the Low Countries was followed by a second break in eighteenth-century Britain as that country's navy and trading companies helped build a global empire and a new class of merchant entrepreneurs emerged. The English share of European urban growth had been 33 percent in the seventeenth century, but was over 70 percent in the eighteenth century, much of it concentrated in London, by now Europe's largest city. London's demand for food radically changed the agricultures of the English core. Dutch engineers were enlisted to bring their technologies to England and facilitated the drainage and settlement of the East Anglian Fens while the import of the "Belgian system" of crop rotation made possible the cultivation of the nation's sandy wastelands. The great city's demand for fuel led to rapid expansion of coal mining and coastal shipping. Britain's urbanization level reached 30 percent by 1800, but in the rest of the world there was little change from 1700. The number of cities with populations greater than 500,000 increased only from five to six and the number of places exceeding 100,000 from thirty-five to fifty. Within the European nations' expanding colonial empires predominantly rural societies were controlled from small numbers of modestly sized coastal centers that were organized around their ports, docks, and warehouses.

Enter Industrialization

By 1800, the new forces that were at work were to radically rewrite the world map of urbanization. In Britain, urban growth was already accelerating outside London, with the main burst of expansion in Manchester, Liverpool, Birmingham, and Glasgow, plus a second echelon of urban areas in the 20,000-to-50,000 range that included Leeds, Sheffield, Newcastle, Stoke, and Wolverhampton. The precipitating factors were technological advances in the cotton and iron industries, the first flush of factory building, and significant improvements in inland transportation with the construction of a canal network. The new urban centers were either mill towns in which the workers resided within walking distance of the factory, specialized manufacturing cities such as Birmingham, or centers of control and finance like Manchester. Demand for labor was fed by rural-to-urban migration as feudal villages were reshaped by enclosures that released surplus labor to the towns.

Subsequent bursts of technological change built on this first surge of industrial revolution to create a new kind of city that was built on productive power, massed population, and industrial technology. By the end of the century, this new city has been credited with the creation of a system of social life founded on entirely new principles. By 1900, the level of urbanization had reached 80 percent in Britain, exceeded 60 percent in the Netherlands and newly industrializing Germany, reached 50 percent in the United States, and climbed to 45 percent in France. Sixteen cities now exceeded 1 million in population, there

All cities are mad: but the madness is gallant. All cities are beautiful: but the beauty is grim. • **Christopher Morley (1890–1957)**

were 287 exceeding 100,000, and the world economy had been reshaped around the great urban-industrial core regions of western Europe and the northeastern United States.

Contemporary observers recognized that something dramatic had happened. Adna Weber, the chronicler of the changes, wrote in 1899 that the most remarkable social phenomenon of the nineteenth century was the concentration of population in cities. The tendency toward concentration, he said, was all but universal in the Western world. The change involved a process whereby, as societies modernized, their market mechanisms expanded in scope and influence. The size of production units increased, as did the number and complexity of production decisions. Increased division of labor and increased specialization, the necessary concomitants of increased productivity, became forces promoting further population concentration and the shift in the occupational structure of economies from agriculture and resource extraction to factory-floor jobs and white-collar occupations. New institutions were created and old institutions were radically altered, especially the financial and market institutions that contributed to the accumulation of social and economic overhead that made further high-level productivity increases in cities possible. There were widening radii of global change as demands for food and raw materials increased and as environments were modified by the unrestricted discharge of effluents, but because of the limitations of foot and horse, the new cities grew, as H. G. Wells put it in 1902, as “puff-ball swells”—dense concentrations within a limited radius of their central business districts. The combination of size, high density, and immigrant-derived heterogeneity had distinctive social consequences: greater individual freedoms and opportunities for social and economic advancement, but also inequality, alienation, and deviance.

Twentieth-Century Urban Growth

During the twentieth century, the urbanization level in economically advanced nations leveled off at 80 to

90 percent but rapid urban growth diffused to most other parts of the world. By 2000, half the world’s population lived in urban areas and virtually all population growth was occurring there as rural-to-urban migration accelerated in countries beginning their process of modernization. More than eight hundred cities had populations in excess of 500,000. Of these, some four hundred exceeded 1 million, of the “millionaire” cities forty exceeded 5 million, and sixteen of these had populations of 10 million or more.

The leveling off of urbanization in the economically advanced world did not mean stasis. New technologies transformed the spatial pattern of urban growth and created new types of transnational urban networks. The concentrated industrial metropolis had developed in the nineteenth century because centrality meant lower costs for specialists who had to interact under horse-and-buggy conditions. But shortened distances meant higher densities, increased costs of congestion, high rents, loss of privacy, and mounting social problems. Virtually all the transportation and communication developments of the twentieth century had the effect of counteracting the constraints of geographic space, making it possible for each generation to live farther apart and for information users to rely upon information sources that are spatially distant. As a result decentralization moved to the fore as the dominant spatial process restructuring urban regions, producing far-flung metropolitan areas and the emptying out of the higher-density cores: commuting radii extended more than 160 kilometers from traditional urban centers and in the most densely settled areas, overlapping urban systems combined to create polycentric “megapolitan areas.” Globally the interdependencies made possible by revolutionary new information technologies enabled increasingly specialized urban areas to link up in networks dominated by “world cities” such as New York, London, and Tokyo—centers of finance and corporate control.

In middle- and low-income countries, freed of colonial controls, the rush to the cities began in the 1960s and accelerated through the end of the century. The combination of low income and inadequate

A street scene in modern-day Mathura, India (population over 2 billion). In ancient times the city was an economic hub located at the junction of important trade routes. Photo by Klaus Klostermaier.

transportation resulted in a repetition of the West's nineteenth-century experience of mounting social problems, even as the new cities became the loci of social and economic transformation. But the difference in scale is notable. Much of the change occurred in significantly larger places. Of a total world urban population of 2.86 billion in 2000, 75 percent resided in developing-world cities. The new population concentrations included two-thirds of the world's 10-million-plus population megacities.

Outlook for the Future

According to *Demographia* (2010) populations and projections listing, the world's ten largest populated urban areas as of July 2010 are: Toyko-Yokchama, Japan (35,200,000); Jakarta, Indonesia (22,000,000); Mumbai, MAH, India (21,255,000); Manila, Philippines (20,795,000); New York City (including

Bridgeport, Danbury and New Haven in Connecticut, and Trenton and Hightstown in New Jersey, 20,610,000); Sao Paulo, Brazil (including Francisco Morato, 20,180,000); Seoul-Incheon, Korea (including Suwon and Ansan, 19,910,000); Mexico City, Mexico (18,690,000); and Shanghai, SHG, China (18,400,000). The United Nations projects that by 2030, 83 percent of the world's 5 billion urbanites will reside in middle- and low-income countries in dense urban networks dominated by twenty-five to thirty megacities. We have yet to learn what the consequences will be, but they will surely be no less radical than those of the nineteenth and twentieth centuries.

Utopia

Although utopias and utopianism are associated with modern Western political literature and social movements that describe a place in which the ideal has become real, they exist in many cultures throughout world history and might be typically categorized as literary, philosophical, or historical.

The word *utopia*, coined by Thomas More (1478–1535) in his political fantasy of the same name, literally means “nowhere” (from the Greek *ou* = no, *topos* = place)—which of course raises the question of whether More believed such a place could even exist—but has come to be applied to any fictional or actual community based on social and political idealism. Utopias have been portrayed in literature and in philosophical treatises, and humans have experimented in creating them throughout history.

Literary Utopias

A frequently documented fantasy in both folk and formal literatures of many different cultures across world history is that of the ideal world in which there is comfort, ease, and plenty for all. Greeks such as Hesiod (c. 800 BCE) and Romans including Virgil (70–19 BCE) and Ovid (43 BCE–?CE) imagined an early stage in human history (the golden age) in which people and gods lived together in harmony. Virgil imagined peasants in Arcadia enjoying effortless agrarian work resulting in nature’s bounty. The Hebrew scriptures’ book of Genesis begins with a similar original golden age in the Garden of Eden,

which most modern readers interpret symbolically but which was considered very real by medieval and Renaissance Christians who speculated about its location.

Idealized lands and kingdoms preoccupied the medieval mind. The Land of Cockaigne was a folk fantasy of a peasant’s paradise—and was also immortalized in a painting by Pieter Brueghel the Elder in 1567—into which the aristocrats or wealthy clergy would not be admitted. The Land of Prester John, documented in the travel narratives of Marco Polo (1254–1324) and John Mandeville (flourished 1356), was a product of the medieval fascination with distant lands. It is surrounded by pagan nations but ruled by a benign priest-king (so it has much in common with the philosophical utopias of Judaism and Christianity).

Philosophical Utopias

Theorizing about the ideal human community has an ancient and diverse ancestry. In *The Republic*, Plato (c. 428 BCE–348? BCE) discussed the necessity for virtuous philosopher kings to rule over virtuous citizens. In *Critias* and in his obscure work *Timaeus*, Plato introduced the world to the legend of Atlantis, a staple of utopian literature even today. The *Analects* of Confucius (551 BCE–479 BCE) collects the Chinese philosopher’s teachings about the right order of society in which the ruler’s and the people’s virtue ensure stability and prosperity.

Judaism, Christianity, and Islam share common traditions relating to an ideal social order. The Torah describes a promised land flowing with milk

The avowed aim of all utopian movements is to put an end to history and to establish a final and permanent calm. • **Ludwig Von Mises (1881–1973)**

and honey, and the prophetic literature of Judaism imagines a messianic kingdom ruled over by a virtuous, priestly king who takes care of the poor and dispenses justice. Christian scriptures similarly imagine a community of believers united under the messianic leadership of Christ. The Muslim Qur'an also describes an ideal social order uniting people of faith, as well as a future paradise for the just and virtuous.

During the European Renaissance, many writers examined the conditions and institutions that would produce an ideal society. Some of these texts would become the template for new experiments in communal living. The most famous of these, of course, is Thomas More's *Utopia* (1516), a fictional account of a traveler who has returned to Europe after having visited an island commonwealth where land is held in common, both men and women are educated, and there is religious tolerance. Tommaso Campanella (1568–1639) combined revolutionary and scholarly insights to write his utopian visions. His *Monarchia messiae* (Anointed King) proposes the establishment of one world ruler and one world religion. *Citta del sole* (City of the Sun) suggests that the head of the ideal city would be a priest-king, like that of the Land of Prester John. Drawing on Plato's *Timaeus* as well as More's *Utopia*, Francis Bacon (1561–1626) imagined an ideal society in *New Atlantis*; its capital, Bensalem, is organized around scientific study and its rulers are scientist-kings.

Historical Utopias

Actual communities based on the principles spelled out in the literary or philosophical utopian traditions have often been attempted. Rarely outliving their visionary founders, utopian communities nonetheless introduce innovations into mainstream societies.

European colonization of the Americas was accompanied by utopian schemes that tried to implement what visionary texts merely described. English settlements in North America, in particular, imagined

themselves as the “new Israel,” or the “new Chosen People.” Puritan Separatists (such as the Pilgrims of Plymouth Plantation) established a theocratic community, which they tried to keep pure by exiling their more wayward members, among whom were those who settled Rhode Island as a refuge for religious dissenters. Similarly, Pennsylvania as a haven for European dissenters and Maryland as a Catholic enclave endorsed the principle of religious freedom that characterized More's *Utopia*. The seventeenth-century English revolution, resulting in a short-lived republic, spawned even more radical social experiments, such as the communistic Diggers and Levelers. The American Revolution may have been a rationalist project (like its protégé in France), but the early Republic became a laboratory for a variety of religious and secular utopian experiments.

If the eighteenth-century American and French revolutions institutionalized political utopianism, the nineteenth century bred its most diverse intellectuals and practitioners. While some of these were religious, like the Mormons and the Shakers, many were secular, like the American Brook Farm Community (the object of Nathaniel Hawthorne's 1852 satire, *The Blithedale Romance*), William Morris's Arts and Crafts movement and the Fabian Socialists in England, and the French utopian socialists Comte de Saint-Simon (1760–1825), Charles Fourier (1772–1837), and Pierre-Joseph Proudhon (1809–1865).

Preeminent among the intellectuals was Karl Marx (1818–1883), who towered above the age both for the extent of his social, historical, and economic analyses and for the breadth of his influence well into the twentieth century. Ironically, the nineteenth-century industrial societies that Marx imagined to be the most fertile ground for his ideas did not produce the kind of revolution he predicted, which occurred instead in agrarian countries like Russia, China, Korea, Vietnam, Cambodia, and Cuba in the twentieth century. Moreover, by developing Leninist and Stalinist models of government, the totalitarian regimes that succeeded these revolutions (and their fascist counterparts in Spain,

Germany, and Italy) encouraged the creation of a “dystopian” literature, including Aldous Huxley’s *Brave New World* (1932) and George Orwell’s *1984* (1949).

Future Prospects

Despite a history of spectacular failures of utopian schemes in the twentieth century, the twenty-first century is likely to continue to witness two forms of utopianism: small-scale intentional communities and large-scale religious utopianism. In the West small, local, intentional communities of like-minded people will persist as a way to resist the values and structures of mass culture, mass economics, and mass politics. Mass culture often makes utopian claims based on its technological advancements, which are driven by consumer capitalism. *Atlantis*, for example, is no longer a Platonic prototype of utopia but a vacation resort in the Bahamas. Similarly, the Western proliferation of the Internet has frequently idealized “cybertopia” with claims of the Internet’s power to transform society, politics, education, and the economy. Digital communism, the notion that digital intellectual property should not be privately owned, will continue to confront digital capitalism. Although the dominant large-scale utopian ideologies of the twentieth century were secular, in the developing world the twenty-first century is likely to witness more frequent attempts to establish utopian theocracies founded on religious principles. Throughout the latter twentieth century, Islamic movements in particular demonstrated a growing disenchantment with the utopian claims of Western democratic capitalism and Communist socialism. The Iranian revolution that overthrew the country’s shah in 1979 and the Taliban’s resistance to the Soviet presence in Afghanistan put into power Islamic republics whose laws were said to reflect the Qur’an and Muslim law, or sharia. The terrorist entity al-Qaeda might be more coherently understood as a militant movement following a utopian ideal. A continuing phenomenon of revivalism in the world’s largest religious

communities (Christianity, Hinduism, and Islam) preaches to audiences who are receptive to a message of clarity and hope (in exchange for obedience). Historically each of these religions has attempted to imagine and to affect a more perfect world. Whether they will do so without coercion or violence remains to be seen.

At the age of eighteen Victoria ascended to the throne after the death of her grandfather, George III. She ruled Great Britain and Ireland until her own death in 1901. Victoria found her niche as a warrior queen during the Crimean War (1854–1856); she remained devoted to the British troops and became the symbol of expanding empire for the remainder of her reign.

Victoria reigned as queen of Great Britain and Ireland from 1837 until her death. Her empire grew to be the world's largest, including at its height 25 percent of the Earth's population. In 1877 parliament conferred on her the title Empress of India. Her nine children married royalty and she became grandmother to European royalty.

Victoria was born to Edward, Duke of Kent, the fourth son of George III, and Victoria, a widowed German princess of Saxe-Coburg. Her parents intended to produce an heir in an effort to have parliament make good her father's debts. After her father died before Victoria was a year old, her mother raised her

strictly in preparation for her inheritance. William IV, Victoria's uncle—her father's older brother—produced no legitimate heirs and so with her father's death Victoria was next in line. Victoria slept in her mother's bedroom until she ascended to the throne. Victoria immediately asserted herself by sleeping alone and by dispensing with her mother's comptroller, who had exploited his position. Estrangement from her mother left the eighteen-year-old queen under the tutelage of her prime minister, Lord Melbourne, who instilled in his charge a strong, unquestioned sense of her central role in politics.

In 1840 she married her first cousin, Prince Albert of Saxe-Coburg-Gotha. Excluding him from governing at first, she came to worship Albert and gradually made him de facto co-regent.

Between 1840 and 1857, they produced Victoria, Edward, Alice, Alfred, Helena, Louise, Arthur, Leopold, and Beatrice; they made every effort to create a model family, teaching duty, hard work, chastity, and sobriety. The family moved among homes at Windsor Castle, Balmoral in Scotland's Highlands, and a new house designed by Albert on the Isle of Wight (Osborne). Named prince consort by his wife in 1857, Albert along with Victoria played a key role in the confused coalitions that governed after Robert Peel destroyed the Tory

Baron Heinrich von Angeli, *Portrait of Queen Victoria* (1877). Oil on panel. Parliament named the queen "Empress of India" the year the baron painted this portrait.

The important thing is not what they think of me. But what I think of them. • **Queen Victoria (1819–1901)**

Franz Xaver Winterhalter, *Queen Victoria [center] and Prince Albert with the Family of King Louis Philippe at the Chateau d'Eu, 1845*. Oil on canvas.

Party to give Britain free trade. Victoria found her preferred role as a warrior queen during the Crimean War (1854–1856), seeing off the troops, visiting the wounded, and establishing the Victoria Cross for bravery in 1856.

Albert died of typhoid in 1861, leaving Victoria distraught and causing her to withdraw from public appearances—except to review her troops. She built memorials to Albert and had servants lay out a fresh suit of clothes in his room each evening for forty years.

In private she allowed John Brown, Albert's Scottish servant, to serve as her comfort until his death. The Conservative prime minister, Benjamin Disraeli, wooed the queen from her grieving isolation and restored her popularity by making her the symbol of the British Empire. Supplying her with political gossip and cabinet secrets, he converted her into an ardent, partisan Conservative. She despised William E. Gladstone, leader of the Liberal Party, and his plan to give Ireland home rule. She exhibited dismay when Gladstone's

government failed to rescue “Chinese” Charles Gordon from Khartoum and approved heartily when General Horatio Herbert Kitchener defeated the Mahdists at Omdurman, Sudan, in 1898. Once she possessed a territory, she never wanted to part with it, believing that any people profited from her rule.

In 1887 Victoria celebrated her golden jubilee as a European monarch with relatives and rulers from across Europe parading through London’s streets dressed in elaborate military uniforms. Victoria excluded the heads of Europe from her diamond jubilee in 1897 to invite the rulers of her dominions and colonies, turning the ceremony into a celebration of the empire’s diversity and might. But the Boer War clouded her final years. Her grandson, William II, Emperor of Germany, favored her enemy and the conflict strained the resources of the empire.

Victoria adopted an Indian Muslim servant, Abdul Karim, as her favorite, demonstrating her “liberal” views on religion and “race.” Though she personally preferred the Scottish Presbyterian service, Victoria constantly strove for tolerance. She valued her relations with all her subjects, caring deeply for her servants and comforting widows of all classes. She displayed a feel for the public mind. Although she considered herself a constitutional monarch and favored free trade, she had her prime ministers write her each day reporting all significant affairs and never

hesitated to intervene when she felt it necessary. She named the Liberal Lord Rosebery prime minister in 1894 because he was a safe imperialist. She influenced the appointment of cabinet ministers and sometimes conspired to elect Conservatives. Though she gave her name to an era popularly known for its prudishness, she forgave drunkenness and other human foibles in those whom she loved. When she died at Osborne in 1901, the world recognized it was the end of an era.

Viking Society

The word *Viking* derives from the Old Norse word *vik*, meaning “inlet,” probably a reference to the Vikings’ habit of using bays, sounds, and fjords—ubiquitous along the Scandinavian coasts—as places from which to stage attacks on seagoing vessels. Through three centuries of sustained military and mercantile endeavors, the Vikings played a significant role in the diffusion of Norse culture throughout Europe.

The Vikings appeared on history’s stage during the eighth century CE. In 793 CE a group of Viking marauders from Scandinavia besieged, captured, looted, and destroyed a Christian monastery on Lindisfarne, a small island located just off the northeastern coast of England. This was the first in a long series of military incursions made by seafaring Scandinavian warriors. During the next two centuries their quest for land and wealth would take them as far west as Ireland, Iceland, Greenland, and the northern tip of the New World. They would make their presence known along the Atlantic coasts of France, Portugal, and Spain. They would also penetrate the interior of Europe via its network of rivers, eventually reaching both Baghdad (Iraq) and Constantinople (Istanbul, Turkey). Paris, York, and Dublin would experience their fury. They would also establish footholds at Novgorod and Kiev in Russia.

Scholars do not know with any degree of certainty what elicited this wave of conflict. But like other popular migrations that have taken place throughout history, such as those that occurred in the Mediterranean basin during the twelfth century BCE and in Europe during the fifth century CE, a common stimulus tends to be a gradual (or radical) shift in weather patterns

that alters the cycle of subsistence. Consequently, scholars have postulated that a significant climatic change in northern Europe produced warmer temperatures, caused glacial recession, and led to two significant environmental anomalies—one biological, the other social. The first was a decrease in the rate of infant mortality, accompanied no doubt by a rise in the male birth rate. The second was a burgeoning population of young males who could neither be assimilated fully into economic life nor provided with sufficient means for survival given prevailing inheritance customs. This perceived lack of resources perhaps fostered an atmosphere of desperation that propelled the Vikings into Europe and the Atlantic in pursuit of conquest and profit. The derivation of the word *Viking* is the Old Norse word *vik*, meaning “inlet.” Thus, the name probably refers to the Vikings’

The Oseberg (*Osebergskipet* in Norwegian), a Viking ship circa 800 CE, was discovered in a large burial mound at the Oseberg farm near Tønsberg in Vestfold County, Norway, 1904–1905.

penchant for using bays, sounds, and fjords—ubiquitous along the Scandinavian coasts—as places from which to stage attacks on seagoing vessels.

Feared for their martial prowess, Viking warriors were equally adroit in military operations on sea and land. They mastered the construction and sailing of the longship, a durable vessel that could reach a maximum speed of 18.5 kilometers per hour and traverse 200 kilometers in a typical day. It was of inestimable value to the Vikings, given the quick-strike surprise tactics that were one of the cornerstones of their military strategy. In ground combat the Vikings employed an impressive array of weapons, including swords, spears, javelins, battle-axes, knives, bows, arrows, shields, and body armor. The average height of a Viking warrior was 1.72 meter, roughly .07 meter taller than most European males whom they would encounter on the battlefield. This physical advantage, along with their skill in psychological warfare, made them a formidable force with which few could reckon. They had even their own cadre of elite military personnel—the Berserkers. Named for their unique attire (bear skins), these operatives

appear to have used shamanic techniques to alter their normal state of consciousness in preparation for combat. Byzantine rulers recognized the prowess of Norse (Viking) warriors and utilized their services in the Varangian Guard, a select unit that provided protection for the emperor.

Religion

Viking warriors had a particularly strong religious attachment to the Norse god Odin, known popularly as the “Father of Victories.” Those warriors who lost their lives in battle expected to be ushered by divine escorts, the Valkyries, to Valhalla, Odin’s palatial hall in the divine land of Asgard. Here they would feast and continue to train for the ultimate battle, called “Ragnarok,” in which the entirety of the cosmos along with its divine and human inhabitants would be destroyed. This final cataclysm would lead to the generation of a new universe, which would be repopulated by a remnant of gods and humans. Odin was considered the patron of war, poetry, and the *futhark*—the runic alphabet. Norse myth records

A Viking tower in the midst of celtic cross markers in a Burren, Ireland, cemetery.

that he obtained the runes (characters of the alphabet) after being hung upside down on *yggdrasil*—the “world tree”—for nine days.

The Norse pantheon consisted of two divine families: the Aesir and the Vanir. The former was made up of the gods living in Asgard. In addition to Odin, these gods included Thor, god of thunder and wielder of the divine hammer Mjollnir; Loki, the divine trickster; and Heimdall, guardian of Bifrost, the bridge leading to the celestial abode of the Aesir. The Vanir lived in the sacred land of Vanaheim and consisted of deities closely associated with the world of nature. The most important of these were Njord, god of wind and sea; Freyja, goddess of love and fertility; and Freyr, twin brother of Freyja and god of sun and rain. In general, the Vikings believed themselves to inhabit a world suffused with the numinous (supernatural) and to be intimately linked with an assortment of spiritual

entities. With the embrace of Christianity, this older stratum of belief would not be eclipsed. It would live on in the popular imagination and the development of syncretistic (relating to the combination of different forms of belief or practice) traditions in religion and the arts.

Mythology

The peoples of northern Europe had a fondness for poetry and an appreciation for its evocative power. Poetry was a particularly effective vehicle for preserving and passing on their myths, epics, and legends. The mythology that helped to shape the social world of the Vikings contained a rich assortment of stories dealing with creation, the exploits of their gods, and the culmination of history. Two thirteenth-century sources provide the context and background necessary for understanding these stories. Together they open a window onto the world of Norse imagination. The first is Saxo Grammaticus’s *History of the Danes* (c. 1215 CE), written from a distinctly Christian perspective. The second is the *Prose Edda* (c. 1220 CE), written by Snorri Sturlson, an Icelandic poet. Viking achievements in the utilitarian and decorative arts were also significant. The former category included their manufacture and embellishment of weaponry (e.g., ships, swords, axes, and shields), utensils (e.g., vessels for drinking), and musical instruments. The

An idealized drawing of a Viking ship on a voyage of discovery to Iceland.

latter category included jewelry such as pins, necklaces, and bracelets. Wood, textiles, stone, and metal were the preferred artistic media.

The Vikings left an indelible mark on Western civilization. Through three centuries of sustained military and mercantile endeavors, they played a significant role in the diffusion of Norse culture throughout Europe. This cultural legacy continues to flourish; some of its ancient lore and rituals having been reclaimed today by religious seekers who use it to fashion neopagan spiritualities. Other elements native to it have long been part of popular Christian practice (e.g., the Christmas tree, which may be a cultural reflex of the Norse *yggdrasil*). Deep resonances between Norse eschatological conceptions (those relating to the final events in the history of the world)

and those of both Christian theology and scientific cosmology promise to make Viking society a source of fascination in the twenty-first century as research into global conceptions of cosmic and human origins continues.

Villages

Villages formed in Asia about 11,000 years ago when humans first adopted agriculture. These “primary communities” have since fostered social, technological, and economic interactions, cultural continuity, and stable child rearing. But increasing urbanization led to the demise of the village. Long-term human survival probably requires that stronger and more village-like communities take root in our cities to nurture growing populations.

Human beings are social. This means a life worth living requires individuals to interact continually with those around them and weave a web of shared meanings and shared feelings that shape and guide each person’s behavior from earliest infancy. Through most of recorded history, and until the twentieth century, villages were the principal place where this human social need was met. The vast majority of our ancestors lived in villages and worked in nearby fields, enjoying the benefits and suffering the pains of living day in and day out with a few score or few hundred fellow villagers in what sociologists call a “primary community.” Cities were different. Strangers abounded, and laws enforced by rulers and their agents were needed to keep peace among strangers. Primary communities of mutual acquaintances still functioned within cities, but only on a part-time basis, since encounters with strangers occurred so often.

Neither villages nor cities existed at first. Nonetheless our ancestors were social even before they invented language and became fully human, so gestures and facial expressions play a part in weaving the web of communication that ties us together and makes cooperation effective. But words and sentences

expanded the scope and precision of communication and made planning ahead possible. Even more important, when expectations were disappointed, people asked why. And then they talked things over, seeking a better way to get what they wanted.

Hunting and Gathering Societies

Planned cooperation and deliberate change when plans failed marked the dawn of full humanity, distinguishing us from all other forms of life. That may have begun about 40,000 years ago when our ancestors began to change the size and shape of their stone tools far more rapidly than before. No one knows for sure.

We do know, however, that before and after attaining full humanity, our ancestors were hunters and gatherers and lived in small bands like those of the hunter-gatherers who still exist in a few remote places in Africa and the Amazon rain forests. Such peoples wander to and fro within well-defined boundaries where they feel at home, hunting animals, picking fruit, digging edible roots, and catching grubs and insects day after day. They sleep outdoors and carry all they possess wherever they go—bows, blowpipes, nets, digging sticks, together with babies too small to walk. In the twenty-first century, such groups are usually timid and often flee from strangers. But when all humans were hunters and gatherers, and weapons were more or less the same for everyone, we can be sure that bands defended their hunting grounds against intruders when they had to, and at special times of the year they gathered with adjacent bands to dance and sing, arrange marriages, and feast together, just as they do in modern times.

This style of life prevailed for most of the human past and in all probability our genetic heritage is shaped by it. We still yearn to belong to a small group of fellow human beings, larger than the immediate family but small enough to know everyone personally, sharing joys and sorrows and thus making life worth living even in times of sickness or hardship.

Village Society

Villages and a new sort of community life dawned about 11,000 years ago when grain farming began both in west Asia and separately in East Asia, where millet and rice rather than the wheat and barley of west Asia were the first important crops. Grain farming required constructing and guarding storage places for the next year's seed. That meant staying in one place year-round, so early farmers soon constructed permanent shelters for sleeping and cooking. These made life more comfortable, and since the farmers clustered their buildings close together for protection and sociability, they created villages. Village farmers worked longer and harder than hunters and gatherers and their diets were more monotonous. Despite these disadvantages, the new way of life spread from its beginning, since farming produced far more food on a given amount of land than grew naturally, and more food sustained more people. Early farmers therefore could easily drive away small bands of hunters and gatherers wherever soils and rainfall were suitable for growing grain.

Not long after farming villages began to spread in Asia and into Europe in this fashion, other farming villages arose in Africa and the Americas, relying on different crops and supporting similarly dense populations. They also spread far and wide within climatic limits. In ensuing millennia, villages spread so widely that all the early centers of farming eventually mingled, exchanging crops, domesticated animals, and innumerable skills.

Long before the European discovery of the Americas brought these agricultural exchanges to their climax, cities and civilizations subordinated most, but not all, villagers to outside control. The subordinated

village farmers were compelled to hand over part of their harvest to landlords and distant rulers. We call these villagers "peasants." Obviously they had to work harder than before and raise more grain than they themselves needed for food and seed. Plows pulled by domesticated animals made that comparatively easy in Eurasia; Amerindian peasants, however, had to depend entirely on their own labor. They were helped by the fact that both corn and potatoes—their most important crops—yielded more calories per acre than wheat and other Old World grains did, with the exception of rice, which also demanded a great deal of human labor.

Characteristics of Village Life

Compared with villages, civilizations and empires were fragile. They rose and fell as weapons evolved and invading armies came and went. Endless political turmoil also had the effect of expanding the frontiers of civilization to new ground wherever farming villages were sufficiently numerous and productive to support states and rulers, together with priests, specialized warriors, merchants, and artisans who provided rulers with what they needed.

Even so, local differences were very great, and no two villages were ever the same any more than were any two cities or civilizations—or individual persons for that matter. Writing about villages in general is therefore risky, all the more so since village histories were unrecorded and accurate statistics were often lacking.

Still, some generalities are obvious or very probable. They are worth describing not as universal certainties but as usual and approximate averages. First, adult villagers needed children to help with the daily household work and to support them in old age. Life, especially for infants, was precarious due largely to disease, so parents wanted to have more than the two children needed to keep village populations steady. Whenever fertile but uncultivated land was accessible nearby, younger sons and daughters of marriageable age could hope to live as well as their parents by breaking in new fields, and perhaps they could form

a new village if their fields were sufficiently far away. That was how farming became so widespread. But once settlers arrived, landscapes filled up rapidly since children were numerous. Sooner or later, land shortages resulted, presenting stark alternatives to young people who could no longer inherit as much land as their parents did.

Subdividing the family farm and intensifying cultivation was sometimes possible, but it almost always meant impoverishment and could not be done more than once or twice. Hiring out to work for neighbors who owned larger farms was an alternative, but hired hands seldom married and lost status and many of life's satisfactions. Emigration to cities and towns in hope of finding unskilled work was a better bet; since diseases were more intense in towns and marriage was less universal, urban populations usually could not sustain themselves without regular recruitment from surrounding villages.

When these alternatives failed, resort to violence was likely. But peasant revolts nearly always failed, sometimes only after reducing the population sharply. Epidemic disease could diminish a population even more rapidly, and so could the ravages of organized state warfare. Starvation due to crop failure was still another risk village farmers faced occasionally. Overall, rural populations tended to increase since births normally exceeded deaths, and new crops, better seeds, better tools, and new skills spread from village to village, increasing food supplies little by little and from time to time.

What ensured this result was the way villagers raised children generation after generation, even at risk of local overcrowding, and took advantage of every improvement in food production that came to their attention. Villages were the cells of human society. They survived while empires and cities came and went. Local disasters never stopped even a handful of survivors from starting to plant and reap again as a matter of course, forming new families and carrying on local traditions, changing when change seemed useful but, above all, resisting it century after century and millennium after millennium.

A second generality is that villagers were never wholly self-sufficient. From the very beginning of agriculture, special kinds of stone could be quarried only in a few places although they were needed everywhere for tools, and a cereal diet also required small amounts of mineral salt to keep human bodies healthy. Luxuries, too—shells, feathers, and colored pigments to decorate bodies and buildings—often came from afar. These rarities reached individuals living where they did not occur naturally either by hand-to-hand gifting from village to village or by sending out special expeditions to collect supplies from known locations—salt from the Dead Sea, for example. A few wandering peddlers may also have carried rarities from village to village and circulated food and other local products even in very early times. No one knows for sure.

Genetic exchanges with outsiders were also necessary to assure health and vigor. Festival meetings where dwellers in nearby villages came together for dance and song, just as hunters and gatherers had always done, allowed for marriages to be arranged, bringing new genes into the community along with new information to be acted on or forgotten as the case might be. In short, villagers were part of a larger human web extending throughout the inhabited world. Occasional contacts extended not only from village to village but to hunters and gatherers and to townsmen. Proof of that is the fact that humans remained a single species even after spreading around the Earth, instead of differentiating into separate species like the birds the nineteenth-century English naturalist Charles Darwin studied in the Galápagos Islands.

Within that web, villagers had most to learn from cities and towns, where strangers came and went, dealing perpetually with one another and generating no less perpetual innovations more rapidly than anywhere else. An early landmark was when farmers first acquired metal tools. Once available, metal hoes, plowshares, sickles, hammers, and other tools spread, since they lasted longer, worked better, and demanded less effort than did tools made only of stone and wood.

Emigration, forced or chosen, across national frontiers or from village to metropolis, is the quintessential experience of our time. • John Berger (b. 1926)

This made human society more complex, however, since metal ores had to be mined, smelted, and shaped by specialized workers, and such workers had to eat food someone else had raised. Moreover, ores, fuel for smelting them, and refined metal had to be moved from where they were found or made where they were needed. And that required transport—initially by ships and animal caravans—and personnel to arrange each transaction; and they, too, ate food raised by others.

This new complexity was organized from cities, for rulers very much wanted metal for weapons and display, and as long as gold, silver, and bronze prevailed they nearly monopolized its use. As far as villagers were concerned, only after smiths learned to manufacture iron did they begin to use that far more abundant kind of metal. Iron became widespread in Eurasia about 1100 BCE, but Amerindians were limited to copper, silver, and gold before 1500 CE, all of which were too rare, too precious, and too soft to make good tools.

As Old World villagers began to use iron tools, larger harvests became easier to achieve, and for the first time the human majority began to benefit from the urban workshops, miners, merchants, and peddlers that made and distributed iron tools among them. Villages, in other words, began to share at least marginally in the market exchanges that pervaded urban society.

Other things reached out from urban centers, too, not least religious rituals and doctrines that blended with diverse older religious practices. Simultaneously, the stream of migration from countryside to town spread village habits and expectations among city folk generation after generation, thus maintaining greater cultural and human continuity amidst ever-accelerating change than could otherwise have existed.

Commerce, Transportation, and Agriculture

The next far-reaching change affecting a great many villagers began in China about the year 1000 CE when

the imperial Song government (960–1279) found it convenient to require peasants to pay taxes in money. To do so, of course, they had to sell something—food, silk cocoons, or any other local product others wanted to buy. Before that time, peasants did sometimes buy items they could not make themselves—iron tools, for instance, and salt, normally paying in kind with whatever was left over after rent and tax collectors had carried away their share of the harvest. These were exceptional transactions, and most peasants most of the time had always lived without using money.

Coins had begun to circulate about 560 BCE in Anatolia and spread from there throughout Eurasian cities and into parts of Africa. As a standard of value, coins could buy anything. That made exchanges far easier since the purchaser got what he wanted even when he did not have anything but coins in hand that the seller wanted to have. The transfer of a suitable number of coins let the seller seek out someone else, perhaps far away, with something for sale that he did want. Accordingly, all parties profited by creating far-more complex and far-ranging networks of exchange than had existed before. Those networks also sustained local specialization in manufacturing and brought local raw materials into the market faster than before, with all the benefits of specialization that the Scottish economist Adam Smith was to analyze in his 1776 book *Inquiry into the Nature and Causes of the Wealth of Nations*.

Since China's rivers and canals provided safe and cheap transportation throughout the Yangzi (Chang) and Huang (Yellow) river valleys, the monetization of many thousands of villages, where something like 100 million peasants lived, led to rapid increases of wealth and skill. In a real sense this marks the start of modern times, for China's example soon spread along the seaways and reached inland wherever navigable rivers resembled China's cheap internal transport. Within Eurasia, western Europe was best equipped by nature to emulate the Chinese. Accordingly, the rise of towns and markets in that part of the world took off less than a century after Song China showed the way.

For the next thousand years, every time transportation improved with better ships, better roads, and

Ghulam Ali Khan, *A Village Scene In the Punjab*. (1820). Watercolor.

better-kept public peace, the exchange of goods and services between villages and cities intensified. This was the time when crops moved most rapidly from one region of the Earth to others wherever climates permitted. Agricultural tools also became more elaborate, and horses displaced plodding oxen from European plow teams because they walked faster. Alfalfa, turnips, potatoes, and other more specialized crops allowed European farmers to abandon the older practices of leaving grain fields fallow every third year and eliminating weeds by plowing them under in summer before they formed seeds. Other parts of the Earth also benefited from new crops and improved methods of cultivation, but we know less detail about these areas, although major advances were fewer than in Europe, even among the ingenious and hardworking Chinese.

Greater participation in urban-based markets, however, had its drawbacks. Wealth increased but so did inequality within the villages as some families prospered and others lost their land. Soon after 1200, in parts of Europe and especially in England and Flanders, cottars who possessed only gardens

began to eke out a living by spending most of their time spinning and weaving wool supplied to them by a town merchant and selling what they had made back to him. They were more like town artisans than farmers, but by growing part of the food they needed in their gardens, they could work for less than town dwellers. Similar arrangements became very widespread in India where millions of rural spinners and weavers made cotton cloth on a vast scale. They clothed India's population, and merchants exported their cloth far and wide since it was the best and cheapest in the world.

Changes to Village Life

Across the Atlantic, Amerindian villages suffered widespread disaster after 1500 CE, when lethal disease brought by Europeans provoked two hundred years of crippling epidemics until survivors acquired a level of resistance to infections comparable to what Old World populations had acquired in earlier times. Millions died before that disaster worked itself out, many village fields became vacant, and Europeans

brought millions of enslaved Africans across the Atlantic to work on sugar plantations. Those plantations were more like outdoor factories than traditional villages. Other previously isolated peoples suffered similar disease disasters as ships started to sail across the oceans of the Earth, but nowhere on the scale or with such drastic consequences as afflicted tropical America and southeastern North America.

In general, intensified connections with the wider world tended to undermine the cohesion of villages. Sometimes new property rights allowed landowners to dispossess peasants and uproot whole communities. This happened in parts of England when raising sheep became more profitable than raising grain. Sometimes, however, new crops opened new possibilities for hard-pressed peasants. For example, in the seventeenth century, American corn reached the Balkans, allowing Serbian, Albanian, and Greek peasants to escape from Ottoman Empire tax collectors by moving to mountain valleys and planting corn on scraps of fertile soil there. But cultivable land was scant in the mountains, and population increase soon made these villages unable to feed themselves year-round. Descending to the plains to work as masons or harvesters was one alternative; using guns to seize the grain they needed was another. The resulting violence became endemic in the western Balkans in the eighteenth century. It recurred as recently as World War II when guerrilla bands in the mountains defied occupying German forces and lived by collecting extra food from farmers in the plains that fed local towns and cities in peacetime.

To be sure, in some parts of the world, there were villages where subsistence farming continued to be little affected by city influences until the late twentieth century. A few villages in remote regions also relied largely on buying and selling to feed themselves. In Russia, for example, Old Believers who refused to accept official changes in Orthodox worship in the seventeenth century fled to remote northern forests where farming was precarious. There they began to make wooden utensils and toys, sending out peddlers to sell them throughout Russia and return with sacks of grain on their backs to keep those villages alive.

In the world as a whole, a new era began after 1750 when cities started to invade villages with cheap machine-made goods. Flowing water and then steam engines powered new machines for spinning and weaving wool and cotton. This began in England and is often called the Industrial Revolution. Subsequently, steam power was applied to other kinds of manufacture, and steamships and railroads accelerated transport capacity enormously. Cheaper, far more abundant and often better cloth and other goods benefited everyone in the long run but brought disaster to innumerable artisans, mainly in cities but also in many villages, especially in India and England. After about 1850, other kinds of new machines for sowing, reaping, and plowing put still further strain on the world's villages, where smallish fields could not accommodate them.

North America, Australia, Argentina, and Russia were where mechanized farming overturned older life patterns most drastically. Nucleated, or clustered, villages had never established themselves among the European settlers in the Americas and Australia, and family farms were already larger than in the long-settled regions of the Earth. When tractors displaced horses in the fields (about 1920), bigger machines moved faster and allowed a single man to cultivate more acres than ever before. As a result, family farms merged to form larger and larger operating units, sometimes still owned by a single family but often by a corporation. The countryside also emptied out, and in twenty-first-century United States less than 5 percent of the population feeds everyone else, with a lot left over for export.

The former Soviet Union (1922–1991) followed a different path. There Joseph Stalin decreed in 1928 that peasant fields must be consolidated into collective farms and promised tractors and machinery to ease old-fashioned hand labor. Resistance was fierce at first. Many peasants slaughtered their livestock rather than hand cows and horses over to managers of the new collective farms. Serious famine followed since tractors did not arrive fast enough to replace horses, and Communist agents seized stocks of grain to feed the cities while leaving too little behind to

Many villagers were lured to cities during the Industrial Revolution with the hope of finding jobs—but wages were low, working conditions often deplorable, and the use of child labor rampant.

feed the angry peasants. Nonetheless, after the first two or three years, tractors did arrive; far fewer workers were needed to cultivate collective farmland, yet harvests stabilized and millions of ex-peasants left the countryside to construct new dams and factories and perform all the other tasks the government assigned them to do.

Official plans and actual performance never coincided exactly, and labor was often inefficiently employed. But at a time when the rest of the world was suffering deep economic depression, Communist accomplishments were impressive. Innumerable individual Russians also undoubtedly found life in cities and at construction sites easier than what they remembered from the village huts of their youth.

The increase in these civilians' consumption slowed after 1936 when arms manufacturing took

precedence over all else. That, too, proved its value when Germany attacked the Soviet Union in 1939, for the Soviet's expanded industrial capabilities allowed the Red Army to survive and eventually to defeat the invading Germans. But collective farms never nurtured many children, nor did Soviet cities. So the forcible disruption of village life in the 1930s had an unsuspected cost, as birthrates fell well below replacement levels. The consequences for the country's society have yet to be resolved.

Where villages were thickest, small fields and village custom inhibited large-scale mechanized farming and allowed most old ways to persist until about 1950. Population growth among villagers in China, India, the Muslim lands, and eastern Europe strained the existing order; warfare, climaxing in two world wars (1914–1918 and 1939–1945), for all the slaughter it entailed, did not do much to relieve rural population pressures.

Consequently, most of the world's remaining peasants were poverty stricken and already demoralized when first radio and then television began to penetrate their consciousness, often through governmental efforts to make them patriotic citizens and reject Communist or other foreign ideas. Where Communists came to power, as they did in China, Southeast Asia, and more briefly in Indonesia, revolutionary governments were no less eager to exploit the new means of communication to win peasant support. Moreover, after the establishment of Israel in 1947, radically reactionary Muslim groups sought to propagate yet another revolutionary ideology. One such movement came to power in Iran, another briefly did so in Afghanistan, and similar groups continue to threaten Muslim rulers and their American backers everywhere.

Outlook in the Twenty-First Century

The upheavals and ideological storms of the twentieth century showed no sign of abating and insofar as they affected the consciousness of ordinary peasants, older customary ways crumpled. Even more subversive was the effect of "mere entertainment" broadcasts

on television in the form of films from Hollywood and India. They flaunted the wealth and glamour of modern cities, and young peasants, especially those who knew they could not inherit enough land to live even as poorly as their parents did, nearly all concluded that old ways were wrong ways. Yet when they left home to live in city slums, they usually found their lives no better. Radical discontent and the espousal of revolutionary ideas are natural under such circumstances. Millions are caught in this trap and their distress will remain a critical feature of world affairs for the foreseeable future.

Demographers believe that more than half the 6.8 billion people alive in 2009 live in cities. It follows that the safety net villages once provided against urban collapse is much weakened. Contemporary economic strategies that support city life, such as flow-through economies (which move goods through the economy in a linear, single-use fashion) and just-in-time delivery (which supplies goods to a manufacturer as needed), are amazingly productive when they work. But such strategies are increasingly precarious; for example, while oil reserves diminish, tractors still require gasoline to assure the harvest on our mechanized farms that feed city populations.

Long-term human survival probably also requires stronger and more peaceable primary communities to take root in our cities as a substitute for the villages where most of our predecessors lived generation after generation. In times past, professional soldiers bound together by drill, poor urban neighborhoods, and religious congregations were the principal primary communities that took shape in towns and cities. None raised children as successfully as villagers did; all three functioned only part-time, and they sometimes

intensified frictions by including only a segment of the urban population.

Cities are still not reproducing themselves, and villagers may follow suit, attracted and distracted as they are by city ways. Time will tell; but as long as we remain social creatures, we will continue to yearn for fulltime membership in a primary community, despite the risk of violence when such communities collide.

The Wagadu Empire was a leading military and political state in West Africa during the first and second millennia CE. Although recognized for developing an advanced agricultural irrigation system and later as the seat of an influential Islamic religious/philosophical culture, Wagadu is best known for its central role in the early intercontinental commercial and trade system, especially for gold production and distribution.

Located in the Sahel, the transitional semiarid ecological zone between the Sahara to the north (a camel pastoralist milieu) and the savanna and Middle Niger River Valley to the south (a peasant cattle pastoralist milieu), the Wagadu or Ghana Empire was a dominant military and political state system in the first and early second millennia CE. (Wagadu is the name of the empire in the Soninke language. The word *Ghana* was one of its ruler's titles, and medieval Muslim geographers named the empire after this title. Although the present-day Republic of Ghana is named for this ancient empire, they are actually located approximately 805 kilometers apart.) It administered a vast area and embraced a culturally and linguistically heterogeneous population. Muslim accounts dating from the late eighth century to the thirteenth century consistently described it as a powerful polity that was particularly rich in gold.

The core area of the empire, whose roots can be traced archaeologically to the first millennium BCE, was the space of its ruling dynasty (the Soninke-speaking Sissay), military and political functionaries, specialized craft and service groups, and its army. The settlement of Soninke-speakers in the area can be dated to the early second millennium BCE, and

the emergence of hierarchically organized polities occurred between 1600 and 1200 BCE. One historically significant feature of the core was its dynamic and expansive irrigated agricultural system. The social organization associated with its complex of intensive farming practices allowed the system to take over cultivable but marginal desert lands and to assimilate other agricultural communities. Another important feature of the core area was the role of the Wagadu military and political elites in production and trade.

According to a late eighth-century source (al-Fazari of Baghdad), Wagadu was 2,000 kilometers long and 160 kilometers wide and was "the land of gold." The conditions for the expansion of the empire and the development of its domestic economy can be tied to its place in the medieval world economy. Ian Blanchard, a scholar of medieval economic history, has written a detailed study of the history of bullion (gold and silver) production and marketing in the Middle Ages that provides useful insights. He relates that during the years from 930 to 1130, an "industrial diaspora" occurred as the major focus of gold and silver production was relocated from Central Asia to Africa and Europe respectively, and a new intercontinental monetary-commercial system began to emerge. Technological changes in the production base of the West African gold industry—namely, the introduction of the mercury amalgamation process—resulted in a dramatic increase in annual gold production. One consequence of this development was the appearance (between 1136 and 1175) of a distinct North African zone of cheap and plentiful gold, extending from the Atlantic Ocean to the Red Sea. The presence of cheap African gold and equally cheap and plentiful European silver led to the emergence of a distinctive

Afro-European bullion market that was characterized by long-term price stability and an “anti-cyclonic” circulation of the two metals. West African gold passed north to the Mediterranean world, and in exchange a countervailing supply of European silver flowed south. The process created an Afro-European market structure that distributed the two metals between the continents. Blanchard goes on to say that the changes in African gold mining and the gold trade permanently established Africa’s position in an intercontinental monetary-commercial system for the next four hundred years. For several centuries the Wagadu Empire had a central role in this system as a distributor of West Africa’s gold.

Extending the Empire

Given its location between the desert and the savanna, the empire had two orientations: one was the northern frontier (irrigated farming and salt production) and the other the southern frontier (rainfall farming and gold production). From the sixth through the twelfth centuries, Soninke-speaking traders, peasants, and political elites moved northward from the empire’s core zone into the southern Sahara to found or to settle in oasis communities. Nomadic Berber-speaking groups were driven out, assimilated, or subjugated.

Because of their social commitment to a specialized set of agricultural practices, when the northern “frontier” Soninke took over new land, they introduced a well-defined combination of intensive cultivation techniques and a particular social-administrative organization.

Southward expansion created a different kind of frontier. Soninke-speaking traders, officials, soldiers, and peasants from the core settled in the Middle Niger Valley and the Lakes region at the eastern end of the Middle Niger Valley—also referred to as the Niger Delta. Oral histories record the names of the towns and villages they founded between the eighth and the thirteenth centuries. Indigenous Mande-speaking fishing communities and rice cultivators were either assimilated or subjugated under a civil administration based on that of the core. Other Niger Valley groups—for example, cattle-herding Fulfulde-speaking pastoralists—became tribute-paying vassals, and local elites were incorporated into the Wagadu imperial system as minor functionaries.

The Capital

In his eleventh-century description of Wagadu, the Andalusian geographer al-Bakri (d. 1094) states that the empire’s capital (contemporary sources refer to the capital as “the city of [the] Ghana”) consisted of two large towns situated on a plain. One town was the residence of the king and his court and officials; the other was the town of Muslims, where there were twelve mosques, salaried imams and muezzins, jurists, and scholars. (Al-Bakri relates that the Wagadu king’s interpreters, his royal treasurer, and the majority of his ministers were Muslims. The king and the majority of his subjects, however, were not Muslims at the time al-Bakri wrote his account in 1068.) The towns were almost 10 kilometers apart, but the road that joined them was flanked by uninterrupted habitations. Archaeologists believe that the ruined city of Koumbi Saleh (discovered in 1913) in present-day Mauritania is al-Bakri’s Muslim town. Excavations reveal what was once a densely populated, fortified city of single and multistoried houses. It was a major

craft and commercial center and possessed a great mosque, which was built in the tenth century.

Beyond the remains of the city's fortifications are cemeteries and the remains of many constructions, including habitations, workshops, and a series of stone watchtowers that stretch for a distance of eight kilometers beyond the city's walls. Beyond the last watchtower was a densely built-up hinterland that stretched a further 12 to 22 kilometers. Extending 100 kilometers beyond the capital are the remains of stone caravansaries (stone inns where caravans stopped), some of considerable size, and an abundance of tumuli and mounds. The largest tumuli represent the remains of towns. Others represent cemeteries, megaliths, and the ruins of villages, fortifications, and workshops. The building styles and material culture of the ruined sites are similar to those of Koumbi Saleh. The size of the capital and the demographic density and the scale of urbanization in the core can be attributed, in part, to the empire's role in the trans-Saharan and intercontinental bullion trading networks.

Economy

Between the ninth and twelfth centuries, cattle herders and millet- and sorghum-producing peasants settled in the lands above the Niger Valley floodplain. Oral histories credit Wagadu governors with constructing irrigation canals and water reservoirs for the purpose of improving agricultural production. Between the eleventh and thirteenth centuries, dry-farming agriculture gradually supplanted floodplain agriculture as the principal farming system in the Niger Valley. Dry-farming agriculture was established by migrant Bamana-speaking peasants who settled on the lands above the Middle Niger floodplain. Specializing in millet production, they represented a new and expanding market for the products of the fishing industry. In this way dry-farming stimulated the fishing industry and incorporated it into a wider commercial network that extended to the Upper Niger gold fields and Saharan oases. The growing Niger Valley population created a new market for Saharan salt, urban craft goods, and trans-Saharan imports.

Labor Control

In the context of an expanding intercontinental bullion market, Wagadu sought to exploit more effectively and systematically the natural riches of the Niger River, principally through the development of the fishing industry, the hunting of aquatic animals, and the trade in these resources. The expanding bullion market was connected to the general expansion of long-distance commerce, including the trans-Saharan trade. Urbanization (population growth in established towns and the founding of new ones) and the growth of urban crafts were crucial both to the expansion of trade and efforts to exploit the riches of the Niger River. During the eleventh and twelfth centuries, new occupational groups of free-status people known collectively as the Somono were created. Drawn from the ranks of the bonded and war captives, the Somono were settled in new villages or in preexisting ones. In obligatory service to the Wagadu ruler, they specialized in river transport as boatmen and in boat building, aquatic hunting, and the production of fish and fish oil. In return for their obligatory services to the ruler, the Somono were granted, by the ruler, a monopoly over certain economic activities within the Middle Niger Valley. If the ruler did not protect their monopoly, they were no longer obligated to provide him with their services.

A concomitant development was the creation of a number of hereditary slave groups. They included blacksmiths, cultivators, fishermen, herders, masons, armed retainers, messengers, and boatmen. Known collectively as the Zanj, they were royal property and were in lifelong service to the king. In this and later periods there were different categories of servitude in the western Sudan, and some of these categories do not have counterparts in other areas of the world. The Zanj consisted of specialized economic groups, each of which was endogamous. They were royal property in the sense that they were obligated to pay "tribute" to the rulers in the form of economic and service activities. They owned property (for example, their instruments of production), and they could also own slaves (just as slaves could own slaves). Their property

was their own and not the rulers, which gives a distinct twist to the condition of servitude in the Wagadu Empire. The specialized economic groups—the Somono and the Zanj—exercised monopolies over their specific activities and occupations, in return for which they paid tribute to the Wagadu rulers.

Long-Distance Trade

The Middle Niger Valley was known to medieval Muslim geographers as the “Land of the Wangara.” In this context, the name Wangara refers to the principal gold merchants of the empire and to the towns they inhabited. (Wangara is a generic name given to long-distance traders, specifically gold traders; hence it refers to an occupational/economic group and an accompanying social status.) The Wangara trade network covered an immense area, joining the entire Niger Valley into a single commercial-craft system, running from the goldfields in the Upper Niger basin in the west to the Lakes Region in the east. In addition to bullion, this system distributed a wide range of products—salt, copper, iron, craft goods, produce, fish, and so on—both within and beyond the empire. Exporting perhaps 13 to 18 metric tons of gold to North Africa under the most favorable conditions and perhaps 4 to 9 metric tons in less favorable circumstances, it was responsible for ensuring the empire’s place in the international bullion market.

Islam and the Empire

The history of Islam in the Wagadu Empire can be divided into two phases. The first phase (eighth to eleventh centuries) belongs to Kharijite Islam; the second (eleventh to twelfth centuries) to Sunni Maliki Islam. Muslims of the Ibadi stream of Kharijite Islam introduced Islam into Wagadu in the eighth century. From that date until the twelfth century Ibadi merchants and clerics settled in the empire’s urban centers, trading and proselytizing. The earliest converts were the Wangara gold merchants. Ibadi-Wangara relations were not only commercial; they

were also scholarly. Between the ninth and eleventh century the Ibadi-Wangara communities produced an influential religious-philosophical culture, which embraced a significant part of the western Islamic world.

The Sunni Maliki phase is associated with the religious reforms of the Berber Almoravid dynasty in North Africa (1039/40–1147). The ruling dynasty and the political elites of Wagadu converted to Sunni Islam in the 1070s or 1080s and joined the Almoravids (a coalition with the Senegal Valley–based Takrur Kingdom; Wagadu joined this coalition in order to take part in controlling the western trans-Saharan routes up to the Maghrib). Thus, Islam became the state religion of Wagadu. The inhabitants of the capital’s Muslim section were Kharijites and Sunni Maliki believers. In the course of the twelfth and thirteenth centuries Kharijites became a minority among the faithful. The Almoravid-Wagadu connection had both a military and intellectual dimension. Writing between 1137 and 1154, the Andalusian geographer al-Zuhri refers to prominent Wagadu scholars, lawyers, and Qur’an readers in Andalusian towns. He also mentions the Wagadu army commanders who traveled to al-Andalus to participate in the jihad against the Christians of northern Iberia.

Decline

By the early thirteenth century Wagadu ceased to be a state system in the political geography of West Africa. The Soso kingdom, a former tributary located along the southern frontier of the empire (late twelfth to early thirteenth century) and then the Mali Empire (mid-thirteenth to mid-fifteenth century) that arose on the Upper Niger River reduced Wagadu to a tribute-paying vassal state. Nevertheless, Wagadu’s core zone continued to flourish until the first half of the fifteenth century, after which it ceased to exist as a political entity.

War and Peace—Overview

According to archeological evidence dating long before recorded history, formerly peaceful neighbors first resorted to warfare to protect their resources and place in the world; since then there have been many other motivations. Even religions that set theoretical limits on violence sanction and justify war's necessity. More contemporary peace movements are often associated with the pursuit of human rights.

Questions of war and peace have dominated politics and philosophy since the dawn of civilization; conquest and resistance have shaped major eras of global development. But while war and peace are from one perspective inseparable twins—two sides of the same coin—the histories of war and peace have not been so symmetrical. History has often been written about war; “peace studies,” on the other hand, are a modern academic invention. (And note which term comes first in this article’s heading.) This asymmetry points to a fundamental question about war and peace: which condition, war or peace, is “normal” and which the aberration? While a historian’s answer might be that both are “normal” as aspects of the past, the question remains current because it implicates debates about human nature and, often, social and political policy. In other words, how one views the origins of war affects how one sees the possibility or advisability of trying to end war. This article will sketch an overview of the historical origins of war, of the major stages in the history of war, and of the landmarks in the less-studied history of peace.

Origins of War

Getting at the origins of war historically is, of course, a difficult task, and controversy surrounds all attempts at providing an answer. Even defining war proves difficult, as what counts as war is built into many interpretations of the evidence. Since written records do not take us to a time before war, historians must depend on archaeology and anthropology for evidence. Anthropological approaches have often involved studying isolated hunter-gatherer peoples living much as our ancestors did thousands of years ago. The Yanamamo of the Amazon basin are a famous case. The very high levels of interpersonal (especially intergender) and intertribal violence that characterize Yanamamo culture have often been taken as evidence that a proclivity for warfare is built into human nature. But recent reinterpretations of the original field studies in light of the broader colonial history of South America have called this reading into question. Far from being isolated, the Yanamamo have been directly and indirectly affected by neighboring (and often more complex) societies for centuries—societies which themselves practiced organized warfare, exported weapons, and in general contaminated the supposedly pristine experiment provided by the Yanamamo, or indeed by any other simple society that managed to survive into the twentieth century. And for every study of a violent tribe, there seems to be a counterexample of a study of a group living peacefully. The anthropological record, at least based on studies of living peoples, is therefore problematic.

The archaeological record poses its own problems, however, because it is far from complete. But the outlines of an answer are beginning to emerge. Skeletal

remains of *Homo erectus*, the widespread ancestor of modern humans, have been gathered from sites across Eurasia dating from between 2 million and 100,000 years ago, and skeletons of *Homo sapiens*, the modern human species, from between 150,000 and 10,000 years ago have been found around the world. Of these several thousand skeletons, very few bear any unambiguous signs of human-inflicted violence, and those that do are isolated cases. In short, if we define war as *organized* human violence against other humans, as opposed to the odd murder, there is no evidence for it before about 8000 BCE. A site in northern Iraq from around that date is the earliest of a type that becomes increasingly common later: a mass burial of several hundred skeletons showing clear signs of the impact of human weaponry. At roughly the same time, unambiguous fortifications also begin to appear in the same part of the world. The evidence spreads from this point of origin and also appears independently later in other places such as northern China.

What conditions characterize the places and times where warfare springs into existence? Not surprisingly, given the times and places involved, the conditions are associated with the emergence of agriculture. A rising population in especially fertile areas and rich hunting grounds began to put pressure on those resources. Nevertheless, populations in such areas, even before full-scale agriculture, became less nomadic, staking claims to territorially defined settlements, a trend reinforced by farming. In addition to putting pressure on resources, the rising population—in terms of both absolute numbers and the density of settlements—led to the rise of increasingly defined social hierarchies and mechanisms of community governance. Even if such developments arose to deal with questions of intracommunity dispute resolution and economic redistribution, they provided the means for a more organized and effective communal response to outside threats, especially in terms of centralized decision making. Finally, in the first case in northern Iraq and in several later cases where war making arose apparently independently, there appears to have been a severe environmental crisis that triggered the move to

In order to defend Paris during the Franco-Prussian War, National Guard units, including women, mobilized to join the action at the front.

military conflict by creating an especially great strain on established resource levels. The result: formerly peaceful neighboring peoples resorted to organized violence against each other to protect their place in the world.

Once the resort to arms had taken place, several additional dynamics reinforced the tendency for warfare to spread rapidly beyond its points of origin, and indeed beyond places where the initial conditions held. For one, it was a successful technique, at least from the perspective of the early winners, who were of course the ones best placed to exploit the new way of life. But perhaps even more important then and thereafter was the interaction of warfare with social class and political leadership. The interests of social elites in hierarchical societies naturally diverged from the interests of the mass of the people, and warfare proved more beneficial to the elites than to the farmers, because the elites were more likely to specialize in the bearing of arms (so becoming warrior elites) and thus to garner the most in terms of glory and riches from waging war.

And as the most intense form of crisis that societies now faced, warfare made strong leadership all the more crucial. Tribal leaders, chiefs, or kings knew this and therefore favored war as policy more than

Disabled veterans throughout history, like the one pictured in this 1917 poster, have often struggled to readjust to civilian life; their plight is one of war's wide-ranging social and cultural effects. The poster announces a National War Relief Exhibition in Pozsony (in modern-day Hungary).

the interests of their society as a whole would have. To paraphrase the sociologist Charles Tilly's famous maxim about states, war made leaders and leaders made war. Finally, once there were war-making powers on the political map, any society in contact with them had to adopt the new mode of organization or risk conquest and extermination. Avoiding warfare was no longer an option, and war became a constant

in human history, complete with fortifications, arms races, and wide-ranging social and cultural effects.

The History of War

How societies made and make war is probably the central question in military history. The question has often been answered in narrow terms of strategy and tactics—the “art of war” and its supposedly universal principles. Technological determinism—the view that available weaponry shaped crucially (and perhaps exclusively) the ways of making war—also has a long historiographical tradition. But modern military history (as well as some ancient writing on war) tends to take a broader view of the question, analyzing the social and cultural parameters that shape war making in particular societies. This is not to deny that the fundamental constraints of economics and technology do not shape warfare—the largest historical patterns certainly can be constructed around such factors—but rather that how different societies make use of technology depends on their preexisting social and cultural characteristics. It is the combination of social organization and technology, in fact, that marks the first two stages of the history of war (“types” might be more accurate than “stages,” because the two existed concurrently and often in symbiosis).

Elites and Commoners

In early sedentary societies, the social division of elites and commoners proved fundamental to military organization, though different states managed the division in different ways. Though masses of conscript infantry might constitute the numerical bulk of a polity's army, a spearhead of warriors who were elite both by training and social status usually made up the most effective and sometimes the only real fighting force. The dominance of elites was reinforced through differential distribution of the best military technology, which meant in the first instance metal weapons, first of bronze and later of iron. A second technology, the domesticated horse, allowed elite warriors mounted on chariots to thoroughly

Yoshikazu Utagawa, *Battle at Kawanakajima* (c. 1848–1863). This woodblock print shows the cavalry from opposing sides engaged in battle during the Kawanakajima War (1553–1564).

dominate ancient battlefields. In time, chariots gave way to riding, but the superior social position of the cavalryman remained, marked by the height from which troopers looked down on foot soldiers and the cost of their mounts.

In later ages, the dominance of often-mounted elites usually survived socially and politically even when the massed infantry assumed central importance on the battlefield. Dominant infantry forces were not the product of technology, but again of social and political conditions. Cohesion is the key to infantry effectiveness, and it emerged in two ways. In certain circumstances, communal service, exemplified by the phalanxes of the Greek city-states, bound foot soldiers together. More often, the emergence of a strong state allowed rulers to raise and train large infantry forces, imposing cohesion from above: this is the model of imperial Rome and China. Variations of state strength, elite dominance, and social structure account for most of the different forms taken by armies from classical times and well into the second millennium CE.

Horse Peoples

But a second model of social and political organization coexisted with the sedentary elite-commons model from early on, and regularly bested the latter's many

variations in combat. Domestication of the horse (and probably the invention of the chariot as well as riding) was in fact a product of the Central Asian steppes, the vast grasslands stretching from the northwestern borders of China into the Hungarian plain. Too dry for agriculture, the steppes instead supported a population of nomadic herders. Hardened by constant competition for grazing lands and inured by their lifestyle to constant campaigning, when mounted on horses and armed with short but powerful compound bows, steppe peoples made fierce and formidable fighters, unconstrained by the need to coddle a class of dependent farmers and unspoiled by the niceties of sedentary life. The mobility and firepower of a large force of steppe warriors was hard to beat tactically.

What they often lacked, however, was political cohesion, as herding provided too little surplus on which to build stable social hierarchies and state structures, and so many steppe forces remained small. Paradoxically, nomad coalitions and protostates grew strongest in proximity to rich and powerful sedentary states, as nomadic leaders used sedentary goods obtained in trading, raiding, and conquest to build and maintain support. The eastern steppe, connected to the west by a narrow corridor between deserts and facing the often-powerful Chinese state, most often generated such coalitions, and movement on the steppe tended therefore to flow from east to west.

Nomadic conquests and alliances regularly affected the sedentary societies near the steppes, at times replacing or invigorating the ruling class and at times spreading destruction, and often serving as a conduit for the movement of goods and ideas. There were other nomadic frontiers: in Arabia, a more static tribal land that erupted only once, though decisively under Muhammad that one time; to the north of the central Mexican civilizations; in the grasslands south of the Sahara; and in a fragmented “inner frontier” in India. All were sources of military manpower and political instability, but the Asian steppes had the biggest impact.

Gunpowder

The long-term demographic trend ran against the pastoralists and in favor of the agriculturalists, however, and after 1500 CE two further developments first reduced and finally eliminated the independent power of the steppe peoples. First was the shift of Eurasian trade routes towards seaborne commerce, a tendency that accelerated rapidly after the age of Vasco da Gama and Christopher Columbus, and that much reduced the importance of the steppes as an east-west link. Second was the spread of gunpowder technology, which in combination with spreading fortifications effectively countered the firepower and mobility that were the nomads’ greatest weapons.

An age of gunpowder weapons extending from roughly 1400 to 1800 CE is a convenient label for the next stage in the history of warfare, but the causal significance of firearms is the subject of much scholarly debate, centered around the related concepts of a “military revolution” in western Europe and the creation of “gunpowder empires” in much of Eurasia.

Again, basic variations in state strength, elite power, and social structure, as well as (increasingly) economic resources, shaped the differences in armed forces in this age, and no area could claim a significant advantage in military effectiveness until perhaps the last half of the eighteenth century, when European methods of drill, organization, recruitment, and logistics began to move somewhat ahead of the pack. But even that advantage was still limited by technologies

of transport and communication that prevented the projection of significant levels of force much beyond Europe itself. Only at sea was the European combination of ships and cannon dominant before the nineteenth century.

Industry

With the coming of the Industrial Revolution, though, warfare entered a new age, as did every other area of human endeavor. While technology was central to this transformation, it was not specific military technologies that were crucial to the transformation of warfare and the emergence of true European dominance globally in the late nineteenth century, though ironclad steamships and machine guns, among other inventions, certainly played important roles. Rather, it was the vastly increased productive and transport capacities generated by industry that, through two centuries of constant innovation and improvement, brought to war the same character that it brought to the economy, politics, and culture: mass.

Mass production of weapons and supplies supported mass conscript armies, inspired by the mass politics of nationalism that had first appeared in the armies of the French Revolution and Napoleon. Mass destruction in two world wars and in the potential for “Mutually Assured Destruction” brought about by nuclear arsenals resulted. “Total War” recognized ideologically the practical effect of weapons systems that reached under water, into the air, and beyond into space: the potential to erase any distinction between the frontline and the home front. War itself had become a global phenomenon.

One reaction to the potential for global destruction made possible by modern military technology has been the decentralization of warfare. Even during the Cold War, most of the hot wars were fought by proxies for the great powers on one side or both. Since the collapse of bipolarity in 1989, decentralization has increased, with a majority of armed conflicts occurring in civil and guerrilla wars below the level of state-to-state war, including the emergence of global terrorism. Conventional wars seem likely, when involving

I know not with what weapons World War III will be fought, but World War IV will be fought with sticks and stones. • **Albert Einstein (1879–1955)**

great powers, to be waged only when the odds in favor of an easy victory are seen to be high, as in the two wars the United States has fought in Iraq; civil conflicts ensure that peacekeeping, too, will continue to occupy the soldiers of rich nations.

The other reaction to the real and potential destructiveness of modern war has been the emergence, since the mid-nineteenth century, of organized peace movements and mass protests against state-led violence. Believing that Mutually Assured Destruction is indeed a mad concept for international relations, opponents of nuclear weapons, in particular, often call for an end to all war.

Histories of Peace

The dialectic between war and peace long predates modern peace movements, of course. The emergence of war stimulated thinking about war, about peace, and about the desirability of either or both and about how peace was to be achieved.

Classical Philosophy

Attitudes to war in ancient philosophy rarely invoke true pacifism, the belief that war is so evil that it should be avoided at all costs. In some warrior-dominated cultures, indeed, warfare was glorified; seeking peace would have removed all hope for glory and obviated one of the ways in which men (always men, for the history of warfare is highly gendered) gave meaning to their lives. Homer's *Iliad* provides a clear example of this outlook, though the *Odyssey* is more balanced, and both recognize the human costs of war. The Indian philosophical tradition raised the elements of such an outlook to the level of high philosophy. The *Bhagavad Gita*, the central story of the epic *Mahabharata*, a sacred text of Hinduism, explains the concepts of law, duty, and cosmic order in terms of a warrior's dilemma about killing his relatives in a looming battle, with the god Vishnu ultimately showing that killing is a warrior's sacred obligation.

Other classical traditions, while perhaps less nonchalant about individual deaths, recognize war as an

evil necessary to the maintenance of order (both internal and external) and required of good rulers and men in the face of threats to both order and freedom or independence. Greek and Roman writers and Chinese theorists of war such as Sunzi share this outlook, which is perhaps simply a concomitant of a secular, state-centered view of the world. For these thinkers, peace was preferable, but war had benefits, including the possibility of ensuring a more secure peace.

The Salvation Religions

Another strain of ancient thought, exemplified by the Hebrew and Persian traditions, sanctioned war even less problematically as part of a universal god's plan for the world and his chosen people. Both of these traditions influenced the salvation religions of Christianity and Islam, whose attitudes towards war and peace are complicated. Although often portrayed as a pacifist religion in its early days, Christianity in effect accepted war as soon as it accepted the existence of the state in the form of the Roman Empire, and pacifism was from the start a minority voice in the new religion. Early Christian thinkers emphasized the condemnation of war implicit in classical views but ultimately saw its necessity for order. When Christianity emerged after Constantine as the state religion, it therefore made a relatively easy transition to sanctioning warfare led by Christian rulers. Saint Augustine had worked out the main tenets of a Christian theory of just war by around 400 CE. This put limits on the proper conduct of war, but questioned neither its necessity nor its justness within those limits. By the twelfth century, a "just war" theory had accommodated the crusades, and holy war became a part of the Western Christian tradition.

Islam was born in war, and gave birth to a Muslim theory of just war that closely resembled the Christian version. The complication was that the mainstream Islamic tradition looked back to the desert past for models, and so had much more difficulty than Christianity in sanctioning the existence of the state. Since the state was vital to the prosecution of war, just or not, Muslim polities sometimes had more practical

difficulty than Christian ones in sanctioning warfare, despite accepting it in theory.

The other major salvation religion, Mahayana Buddhism, has much less to say about war in explicit terms. Unlike Christianity, which came to prominence with Constantine's military victory under the sign of the cross, Buddhism spread in the wake of the Mauryan emperor Asoka's conversion in the third century BCE, prompted by the horrors of his conquest of Kalinga, and so did contain a strong pacifist tendency. Yet Buddhist states, such as Tibet, and Buddhist warrior classes, such as the Bushido of Japan, both managed to reconcile religion and warfare, and it is perhaps more accurate to say that Buddhism encourages individual quietism, politically, rather than state pacifism. In sum, the effect of the salvation religions on warfare was mostly to put theoretical limits on the conduct of war, but within those limits to sanction and justify warfare. Peace remained an ideal more preached than practiced.

Cultures of War

In practice, limits on warfare were more likely to emerge from particular cultural practices than from overarching religious systems. Most cultures since warfare began have imposed limits on what was and was not acceptable, both in declaring war and in prosecuting it. Rules might govern the treatment of noncombatants and the ransoming of prisoners versus killing them; convention (as well as logistics based on weather and the rhythms of agriculture) might limit campaigning seasons to certain times of year. Certain weapons or ways of fighting might be taboo, quite literally. Ritual penance often served as an obligatory aftermath of killing in war. While often connected to or interpreted within a framework of religion (including the salvation religions), such limits tended to be localized and displayed the malleability of custom and tradition.

Many of the most destructive wars in history resulted from the breakdown of such norms of warfare, either because of "cheating" by an internal player in the cultural system or, more often, because of the

During the Boer War in South Africa (c. 1900) five British soldiers pose with rifles; the woman holding the flag symbolizes the British Empire they protect.

intrusion into the system of an external invader who did not know or play by the rules. Warfare that crossed lines of culture, in other words, tended to be bloodier than intracultural warfare, whether the lines of culture were drawn along linguistic, religious, ethnic, or class lines. Whether it occurred in the warfare of Greek city-states in the wake of the Persian invasion, in the European conquest of the Americas, or in the eruption of terrorism into New York City in 2001, the breakdown of an unstated but pervasive set of rules of war has usually stimulated both the most vehement calls for further war and the most impassioned pleas for peace—from Aristophanes' *Lysistrata* to Bartolomeo de las Casas's arguments in favor of *los Indios* to modern antiwar movements.

Terrorism is seen to violate norms that have acquired the force of international law, and the formalization of ritual limits on warfare, not just in law but in regulated systems of diplomacy, has also served at times to mitigate the effects of warfare. The nomad-sedentary frontier was a frequent site of both breakdowns of warrior convention and the construction of diplomatic ties that created new, broader cultures of acceptable war. While the inherent instability of the steppes often rendered such efforts impermanent, longer-lasting state-based systems of international

diplomacy and understanding have perhaps worked to greater effect, and have produced in the twentieth century mechanisms such as the U.N. aimed at creating a global culture of peace rather than war.

Modernity: Beyond War and Peace?

The rise of modern peace movements as an aspect of mass politics and in reaction to the destructiveness of modern war has often been associated with other modern political movements aimed at expanding human rights generally. Jane Addams, best known as the founder of Hull House and for her efforts for women's suffrage, also worked for world peace; Gandhi used nonviolent resistance against British imperialism and worked for peace; and Martin Luther King Jr. adopted Gandhi's tactics to work both for civil rights and against U.S. involvement in Vietnam. While the work of individuals and even groups in promoting peace may seem unrealistically idealistic against an ongoing backdrop of civil wars, terrorism, and rogue nuclear powers and in the wake of the bloodiest century in human history, there are trends that seem more hopeful.

Political scientists like to point out that no two democracies have ever gone to war with each other (the Civil War between the United States of America and the Confederate States of America forming a controversial exception), and the world at the turn of the millennium is more democratic than ever before. The economists' version is that no two countries with McDonald's have gone to war with each other (although NATO did bomb Belgrade); perhaps increasing global interdependence through economic ties tends to mitigate warfare. On the other hand, environmental crises played a role in the origins of war, and they may play a role in its continuation in the twenty-first century. What is certain is that questions of war, peace, and human rights are now global concerns.

Warfare—Africa

Distinctive shifts in African modes, causes, and experiences of warfare can be traced to European colonialism and the rise of the transatlantic slave trade. Traditional African warfare was transformed by fighting against colonialism, and in fighting as European agents on behalf of colonialism. But contrary to popular myth, warfare is no more intrinsic to Africa and Africans than any other places or peoples.

As is true for human societies everywhere, almost all African societies have had many experiences of conflict that escalated into various forms of warfare. A few behavioral theorists have speculated that the earliest hominid and human communities, which arose in Africa, were initially formed in the crucible of violent conflict. While controversial, such theories have had a major impact on the public imagination since the late twentieth century; these ideas may well have shaped the stereotype that Africans have—from earliest times until the present century—been almost hopelessly trapped in cycles of intercommunal war and violence. The history of warfare in Africa, however, does not bear out this gloomy vision.

Traditional Warfare

Many African societies have held a special place for martial specialists, or warriors. In and of itself, however, the role of such specialists is not necessarily evidence of widespread warfare on the continent before the arrival of Europeans. At the same time, it does suggest that Africans were prepared for various wars and other violent conflicts. The warrior classes often provided training and testing grounds for societally

valued traits of masculinity, while at the same providing means of defending the populace from any external threats. In some cases these threats involved political challenges to established leadership or efforts to subsume additional people into either an established or a new sociopolitical orbit. But frequently the point of such traditional conflict was acquiring wealth, often cattle. In eastern Africa, for example, Jomo Kenyatta, the first prime minister and president of Kenya, recalled that for the Kikuyu, warfare was sometimes little more than “a form of stealing by force of arms” (Kenyatta 1938, 198).

For many Africans the mystique of warfare was bound with ritual and magic. Warriors frequently displayed their prowess both in ceremonies, including dance and musical performances, and in more private rituals, sometimes associated with limited-membership groups or secret societies. The exploits of traditional African military leaders were often extolled in public recitation of their deeds. Frequently these included magical explanations of their successes, calling upon the spirit sources of their strength and other abilities. Such were the stories told of the great warrior and national leader Sundiata (d. 1255), founder of the Mali Empire, by the Malian griot (storyteller) Mamadou Kouyate. Despite significant traditional support for warfare, there was little in the experiences of traditional warfare to prepare Africans for the challenges of warfare presented by expanding external demands for economic advantage or political power.

Impact of the Slave Trade

While some African wars traditionally resulted in the capture of human beings and the absorption of those

A stockade around a village in Africa in the 1800s built to protect the residents from human and other predators.

individuals as productive members of their captors' societies, external demands for slaves occasioned a transformation in these patterns of African warfare. Islamic sources make clear that African societies were willing from an early time to adjust their patterns of war to encourage the capture of people who could be sold as slaves. But it was the almost insatiable demand of European traders for slaves from the sixteenth century onward that transformed African warfare in material ways. In particular regions, such as the eastern frontiers of the kingdom of Kongo and the grasslands and scrub forests of west Africa south of the Sahara, the devastation caused by increased warfare was especially significant. Even after opposition to the Atlantic slave trade grew in Europe, in order to satisfy the demand for slaves in Arabia and on European-settled islands in the Indian Ocean, warfare in the search for slaves continued well into the nineteenth century in other regions.

The latter effects of warfare inspired by the demand for slaves was responsible for one of the great ironies of colonialism, the call for European intervention on the African continent to end persistent African warfare. This was the basis of appeals made by the missionary David Livingston (1813–1873) for

British involvement to bring the benefits of Christianity, civilization, and legitimate (as opposed to slave) commerce in eastern and southern Africa. These calls were made at a crucial time, when both literacy and the availability of low-cost popular publications were shaping the awareness of many Europeans about the African continent. These ideas first set in place notions of widespread African warfare, which were exacerbated by later developments in colonial policies regarding Africa.

Colonial Warfare in Africa

Chief among the results of calls for ending African warfare were military expeditions to “pacify” African peoples and bring them under the “benevolent” control of European powers. In two divergent ways, these efforts also involved Africans in new experiences of warfare. One was a reorientation of African military efforts to oppose the expansion of European interests on the continent. For the most part, Africans were ill-equipped to counter the increasingly technological forms of warfare they confronted. Few African armies were able to successfully repulse European incursions, although some had occasional successes, as did the Zulu *impis* (regiments) in defeating British troops at the Battle of Isandlwana in 1879, an important early battle in the Anglo-Zulu war. But as the saying goes, while the Zulu won the battle, the British ultimately won the war. Nevertheless, the defeat of the better-armed but poorly deployed British by the superior numbers and strategy of the Zulus marked the worst defeat for the British in battles against native forces. The success of the Zulu can be partially attributed to the innovative military reforms of the Zulu Kingdom under the leadership of Shaka (c. 1787–1828). Only the Ethiopians, under Emperor Menelik (1844–1913), were fully successful in warfare against European powers, turning away Italian invaders at the Battle of Adwa in 1896.

The second new military experience tied to colonial expansion was the effort to turn Africans—and especially those from what European colonialists presumed to be “martial races”—into soldiers of

colonialism, transforming them into the very troops needed to first create and then enforce colonial domination in many areas of the continent. Among the earliest of these colonial military units was the British King's African Rifles (KAR), soldiers recruited from east and central Africa. KAR (and other similar) units not only preserved the colonial peace within their own territories but often were sent to other parts of the continent to enforce colonial rule. This practice of co-opting colonial Africans as the military agents of colonial warfare represents a historical turning point in the impact of warfare for Africans.

Africans and the World Wars

In many ways, the culmination of this transformation came as colonial powers sought to utilize colonial troops in their own defense when facing the daunting military challenges of the twentieth century. The European warfare that began in August 1914 was in large part brought on by colonial rivalries and soon spilled over into those colonies, especially in Africa. Minor campaigns brought modern warfare to several areas of the continent for the first time, and the East African Campaign actually continued until several days beyond the armistice in Europe. Perhaps as many as 2 million Africans were drawn into military service during that war as both soldiers and military laborers. France also relied upon African troops for the defense of its home front, and Britain sent thousands of South Africans to Europe as laborers. These experiences—both directly for participants and observers as well as indirectly for those who later heard about them—brought the reality of modern warfare fully into the African consciousness.

With the advent of renewed warfare between the European powers in 1939, Africans were again recruited for military service. Their most significant deployment on the continent was during the North African campaigns, where large numbers were trained as truck drivers. Other Africans served overseas, many in campaigns to repel the recent Japanese conquest of Southeast Asian territories as well as with units sent to Europe in the effort to turn back Nazi

occupation. On returning home, these men frequently felt dissatisfied with the rewards they were given for their service; not infrequently they were soon after involved in various protests against continued colonial domination in Africa.

Contemporary African Warfare

One of the responses to these protests by former soldiers was the expansion of colonial military units and the advance of some Africans to officer corps. Thus, when the protests led to independence for many African colonial territories—sometimes relatively peacefully, for others rather bloodily—the resultant new states came with ready-made national armies. On the one hand these armies served as agents of nation building, employing increasing numbers of citizens and frequently engaging in public-works activities. But on the other they were frequently agents for the settling of various disputes, both real and imagined, which came with the demands of European-induced concepts of sovereignty and nationality. In this context, any number of perceived slights or even ethnic differences could—and sometimes did—escalate into warfare.

The resulting pattern of conflict, well-known from earlier examples of developing European nationalism, was civil war, mostly notably in Congo, Angola, Nigeria, Ethiopia, Mozambique, and Rwanda. Other African countries, including Uganda, Sierra Leone, and the long-independent Liberia, faced internal rebellion. Significant international peacekeeping efforts—including important initiatives of the Organization of African Unity (and its successor, the African Union)—helped to reduce this new form of African warfare. Perhaps more significantly, other African countries, such as South Africa managed to avert postcolonial warfare, breaking the pattern of national violence that has plagued European nations since the sixteenth century. Even at the beginning of the twenty-first century the legacies of colonialism and the struggle for power are still to be fully played out. Established as a Belgian colony, the Congo (officially Democratic Republic of the Congo) in particular

remains a violent and dangerous place where rape has become a weapon of war. The Darfur region of Sudan is plagued by claims of genocide. Somalia remains a state on the verge of failure and at the mercy of warlords. And in Zimbabwe a new generation of leaders is seeking to take over from a corrupt regime still clinging to the successes of the liberation movement of decades earlier.

Warfare—Air

Air warfare has had the greatest effect over the shortest period of time in military history. From hot air balloons and dirigibles to bombers, fighter jets, and unmanned spy planes, the nature of war changed because of aircraft. But the goal of air warfare has remained basically the same: to supply reconnaissance and support to ground troops.

Air warfare refers to military operations above the ground, including tactical support of land forces, transport of troops and matériel, and enemy observation through reconnaissance. In military history, air warfare has had the most profound impact over the shortest time. Early beginnings may be traced to late eighteenth-century France, where paperhangers Joseph and Étienne Montgolfier launched the first hot air balloon. The French Revolutionary army incorporated a corps of balloonists, and the concept of air warfare was born. It was utilized exclusively for observation purposes for a century. By 1900 all major armies included balloon sections and experimented with dropping some form of bombs.

David Schwarz, a German, built and flew the first dirigible in 1886. Count Ferdinand von Zeppelin perfected the new technology and demanded that his design specifically be applied in warfare. Another German, Otto Lilienthal, was the first to scientifically study wing structures and mathematical formulas explaining lift, but it was the American brothers Orville and Wilbur Wright who brought about the instrument that became the primary weapon for air warfare. Their airplane hit the world stage with the first flight on 17 December 1903 at Kitty Hawk, North Carolina.

Formal military use dates from 10 February 1908, when the U.S. Army Signal Corps ordered the first airplane and hired the Wright brothers to instruct two officers. The Frenchmen Henry Farman and Louis Bleriot proved the airplane's long-range capability by flying across the English Channel in 1909. They established the first flight schools in France, which took the initiative among all nations in the promotion of aviation. Germany pursued the development of airships, but in 1911 the government contracted with Albatros to build airplanes for military use. The same year England created the Air Battalion of the Royal Engineers. All European nations followed suit with some form of aviation.

Italy claims a series of firsts in the use of aircraft in military situations, all achieved when it used an airplane for observation on 23 October 1911. An Italian aircraft dropped the first bombs, had the first aviator wounded in combat, and developed the first use of radio communications in flight. As the experimental stage of aviation ended, the organizational structure was in place for the sky to become the next battlefield.

Several small European wars in 1911 and 1912 provided the testing ground for the airplane as a war machine. These included Italians and Turks fighting in Libya, the Mexican Revolution in 1910, a 1912 uprising in Morocco that was put down by France, and incidents in the Balkans between 1912 and 1913.

World War I (1914–1918)

Air warfare came into its own with the first major war of the twentieth century. In 1914, one thousand airplanes were in the service of the major powers;

U.S. bombers over Germany in 1943. Allied air supremacy was a key factor in defeating Germany.

five years earlier there had been none. Observation balloons marked Allied and German fronts. Their purpose was to direct artillery fire. Once the war bogged down in trench warfare, stationary balloons became easy targets of enemy aircraft. The mobility of the airplane came to the forefront, in areas that ranged from intelligence gathering to directing artillery fire. Two-thirds of the French resources were used for artillery spotting.

Air power had no precedent in military history. Two-thirds of the French resources went to artillery spotting use. Aircraft was something new, and while commanders understood some of its functions, full recognition of its strategic value came slowly. The French formed the first bomber group in late 1914, but both they and the British concentrated on developing slow and stable observation craft like the BE2 and Voisin for photography and artillery spotting, while the Germans developed bombers to attack Allied trenches. Even before the war, military strategists recognized the psychological and material damage that could result from bombing. Targets were supply and communication lines, transportation, and troops. Bombers became an extension of the artillery, because with aerial observation, enemy troops could no longer shelter from artillery fire.

The first frontline use of the airplane occurred in August 1914, when the British Royal Flying Corps used two-seater Avro observation planes to cover their lines when Germans attacked their infantry near Amiens. The pilots observed German infantry encircling British infantry and promptly reported this, allowing commanders to redeploy troops and avert a disaster, proving the vital and efficient use of aircraft for intelligence. This simple observation and report would have taken two days to receive from ground patrols.

In July 1913 Captain Alessandro Guidoni of Italy successfully dropped a 100-kilogram bomb. The Russian Igor Sikorsky developed the first four-engine plane in 1914 and flew it more than 2,250 kilometers. By October 1914, the Royal Flying Corps called for all observation pilots to carry bombs. German airships struck at the heart of Britain, bombing London with some 270 kilograms of high explosives and incendiary bombs. Reprisals were carried out on towns, and for the first time, civilians and prominent personalities were targeted—Kaiser Wilhelm on 1 November 1914 by the British and later Czar Nicholas II by the Germans.

The year 1916 was a critical one for the technology of air warfare. Zeppelins became easy victims of

American liberator bombers and P-40 fighters at a base in China, 1943.

British and French antiaircraft guns and bombers. Germany developed the Gotha, a long-range bomber capable of flying at nearly 5,000 meters. The first Gotha raid on 25 May 1917, in a tight formation, heralded a major advance in air warfare and forced profound changes in the concept. By the end of 1917, attacks on major cities were common. Better bombs were developed that were not subject to things like wind drift, and bombsights were perfected to account for factors such as aircraft speed and altitude.

The swiftly changing nature of the war ramped up aircraft technology and played a major role in the evolution of tactics using aircraft, virtually overnight. To protect bomber formations, the fighter was born—pursuit aircraft, or “scouts,” such as the French Nieuport and German Fokker. The “age of aces” dawned. Fighter pilots became public heroes and celebrities. Their role not only stirred the public imagination, their individual skill perfected the art of air combat tactics. The fighter pilot became an interceptor and escort to protect the slower and more vulnerable bombers and reconnaissance craft. They claimed the highest attrition rate of any arm of the service.

Early on, pilots armed themselves with revolvers or infantry rifles, until the invention of the Lewis gun by the American Isaac N. Lewis in 1911. Weighing only 11 kilograms it was quickly adapted to aerial combat. The French Hotchkiss and British Vickers came

later. The Allied concept of aerial warfare changed from bombing or reconnaissance missions to actually fighting enemy aircraft. In 1915 the Dutchman Anthony Fokker developed interrupter gear fitting the machine gun to a German airplane’s Mercedes engine and allowing it to fire on the axis of the fuselage, a major leap in the efficiency of air warfare. In 1916, the fighter arm of the air services evolved from single daring pilots targeting the enemy in a dueling fashion to formations of long-range fighters escorting bombers deeper into German-held territory. The French Air Service implemented this formation concept at Verdun in 1916. In early 1917 Germany created Flying Circuses, which were several squadrons bound together into as many as fifty machines to conduct offensive operations at points along the British sector. From 23 to 29 March 1918, the Royal Flying Corps and the Royal Naval Air Service carried out the first large-scale use of air power impacting the outcome of a battle when seventy aircraft led low-level attacks that caused the German offensive to falter.

The physical battlefield of the air spawned doctrinal guidelines and tactical principles that were published and distributed throughout the air services, especially with the introduction of formation flying. No radio communications existed between pilots and ground forces. Speed was hard to regulate. Pilots were dependent on their commanders’ signals, while still

vulnerable to attack from enemy aircraft overhead. Since two out of three air battles took place behind German lines, going down meant certain capture.

By 1918, an air force existed as a separate entity in the defense forces of every major power. Airplanes revolutionized warfare forever, by removing the element of surprise from the battlefield. Technology had gone from flimsy, linen-covered machines armed with rifles or revolvers, capable only of 100-kilometer-per-hour speeds and 3,000-meter ceilings, to powerful tools of war carrying over 450-kilogram bombs. Duel-like “dogfights” gave way to killing machines like the German DVII, French Spad, and British SE5 and Sopwith Camel, armed with two machine guns firing eight hundred rounds per minute, and flying up to 250 kilometers per hour at 6,700 feet in formation. Aviators were a new breed of soldier, signifying a relationship between man and machine that characterized all future wars. The legacy of innovative pilots like Oswald Boelcke, Albert Ball, Edward Mannock, Billy Mitchell, and Eddie Rickenbacker essentially remained at the core of aerial warfare for sixty years. Also, the Women’s Royal Air Force was organized in April 1918, incorporating women into the military for the first time.

Between the Wars

The golden age of flight advanced military aircraft little. By the late 1930s, Germany and Japan led the world with the most modern air force, having more than fifty thousand planes each, while the United States and its allies had fewer than ten thousand mostly outdated machines. Hermann Goering pioneered the next phase in air warfare with the German Luftwaffe. The Spanish Civil War in 1936 provided an opportunity to develop dive-bombing tactics, and monoplanes replaced biplane design, producing such fighters as the Messerschmitt Me-109 in Germany. But tactics in the Second World War began virtually where they had left off twenty-two years earlier, except the machines were far more advanced. The British Spitfire fighter, introduced in 1938, could go more than 550 kilometers per hour and had a ceiling

of over 12,000 meters. Sir Hugh Trenchard of the Royal Flying Corps and the Italian army officer Giulio Douhet were the chief European proponents of strategic bombing to destroy enemy centers.

World War II (1939–1945)

World War II began with land and sea campaigns. Airpower played a subordinate role, supporting land forces. Germany invaded Poland in 1939, bombing its major cities and destroying its air force. Germany’s blitzkrieg attack on London in 1940 was the first battle fought exclusively in the air. British fighter pilots recognized the same tactics applied that their forebears had perfected in 1917 and 1918: the fighter going one on one with the enemy bomber. England developed strategic bombing capability while Germany concentrated on more cooperation between ground attack aircraft. The Japanese attack on Pearl Harbor on 7 December 1941, using precision reconnaissance and fighters armed with torpedoes, destroyed most American combat aircraft in the Pacific, and proved that aircraft would be a premier tactic in modern warfare.

The Second World War built on the lessons of the First, though many ideas had become obsolete. For the Allies, twelve-man fighter squadrons protected supply lines against the Japanese fleet in the Pacific. The development of radar by the British in 1939 changed the element of surprise. Radio communication advances allowed immediate contact with pilots and ground control to pinpoint enemy aircraft in flight. Long-range strategic bombing became the most effective way of destroying German capability, using the B-17 and B-25 bombers in formation, in such operations as the 1,000-plane raid over Cologne in May 1942 and the Regensburg-Schweinfurt mission in August, launched from bases in England. Since escort fighters did not have the range required, bombers carried their own defenses, like the B-17 with a ten-man crew armed with .50-caliber guns. Gliders were first used for silent troop drops, and P-51 Tankbusters were very effective against German panzer divisions.

Bombs do not choose. They will hit everything. • **Nikita Khrushchev (1894–1971)**

Transport pilots played an important role. The Chinese army was resupplied by air—one of the greatest military achievements in history. Allied forces used C-47s to drop troops to penetrate enemy-occupied territory. On D-Day, 6 June 1944, paratrooper forces dropped from airplanes led the Allied advance on Berlin to end the war. Brave pilots in rugged machines proved that air warfare dominated the outcome on the ground. A leap in aviation history occurred with the first fighter jet, developed by Germany, the Messerschmitt ME 262. Other German developments indicating the future were the V-1 pilotless jet-propelled rocket carrying nearly 2,000 kilograms of explosives, and the V-2, the first guided missile capable of carrying 750 kilograms of explosives more than 300 kilometers. These were launched against England in the summer of 1944, but came too late to affect the final outcome of the war.

Aircraft carriers were used effectively in the Pacific during the Battle of Midway in June 1942, and B-29s overwhelmed any Japanese home air defense. On 6 August 1944, the B-29 *Enola Gay* dropped the first atomic bomb on Hiroshima, ending Japan's war efforts without invasion, and epitomizing absolute air superiority.

Postwar and Vietnam

The development of the jet engine and surface-to-air and air-to-air missiles changed the complexion of air warfare, but the piloted fighter jet played the major role in the Korean War (1950–1953). U.S. single-seat jet fighters, the F-80 and F-86, fought Soviet-built MiG-15s—both able to reach the speed and height required for air fighting, but their supersonic speed made formation flying near impossible. Once again, pilots fell back to the fighting unit introduced by Oswald Boelcke in 1916, the pair. The fighter was used for offensive and defensive day fighting, visual and photographic reconnaissance, and bombing and strafing ground targets.

The Vietnam War (1957–1975) was largely a guerrilla war fought in jungles. B-52 bombers were used for main air strikes against Communist targets, but helicopters became an important aerial warfare technique

because they could easily strike targets in the jungles and mountains. Primarily the air war was between jet fighters, the Russian MiG-17 and MiG-21 jets against American F-105 and F-4 fighters. The surface-to-air missile (SAM) antiaircraft weapon, equipped with laser-guided bombs, missile detection, and radar-jamming devices, posed a new threat to aerial reconnaissance and bombing. Better aerial refueling techniques extended the range of combat aircraft.

Modern Air Warfare

With the advent of computer technology, weapons systems have become more and more sophisticated and “smart.” But the quest for height and the need to establish immediate air superiority remain primary battlefield objectives for air warfare. The Persian Gulf War (1991) and early twenty-first century operations in Afghanistan and Iraq employed the latest technology in the air to control the war on the ground. Stealth fighters like the F-117 Nighthawk, with a range of 1,200 kilometers and carrying two laser-guided bombs, and the B-2 Heavy Bomber deliver surgical strikes on pinpointed targets. By deflecting radar, the Stealth bomber appears invisible to enemy forces. Its four engines hidden in the fuselage enable it to evade heat-seeking missiles.

With such undetectable machines and computer technology, pilot skills and aircraft speed are not issues. Reconnaissance is still a predominant factor in air warfare. Unmanned predator spy planes are the ultimate reconnaissance aircraft, guided by remote control from ground stations and endangering no lives, to dispense real-time information for directing troops and warplanes. C-130 gunboats are essentially airborne artillery, echoing the early days when biplanes were used in conjunction with artillery batteries. The Apache attack helicopter can account for twenty tanks in one strike.

The latest U-2 spy plane flies at more than 25,000 meters, at the very edge of space. The Eurofighter is a state-of-the-art fighter plane. But the ultimate goal of air warfare remains the same as that original concept one hundred years ago—a continual battle for the air,

through height and speed, to supply reconnaissance and support to ground forces.

Warfare—China

Before the nineteenth century, China's wars were waged either internally or with the nomadic peoples along its borders. In further contrast to other nations, China never glorified its warriors, and the protection and defense of towns mattered more than offensive military tactics. Since the nineteenth century, though less isolationist than before, China has fought only to defend what it (broadly) considers its own interests.

China, until very modern times, never faced an equally powerful, proximate civilization; warfare alternated between a unified China contesting with nomadic peoples on its borders and a China divided in internal conflict. Warfare also alternated with the yin and yang of Chinese imperial power. Nomadic peoples never have exceeded several percent of China's population, and while they might conquer China, they could rule only by Sinicizing themselves.

China favored a model of warfare that combined military arts with psychological factors, including an indirect approach to battle, surprise, and deception. The result is the classic *Sunzi* (dating to China's Warring States era, 475–221 BCE) and some 2,500 years later, the theories of Mao Zedong (1893–1976) on peasant revolution and unconventional warfare. Defense, especially the building of walls around towns (the most famous such defense being the Great Wall), mattered more than offense. Also, China has never glorified its warriors, and few left memoirs such as Caesar's accounts of his battles in Gaul.

We know little of warfare in China prior to 600 BCE. China's Zhou dynasty (1045–256 BCE) ruled largely through familial and semifeudal relationships,

not awesome military power. Sometime in the early eighth century BCE, the Zhou began to decline, and in 771 BCE invading nomads allied with rebel leaders sacked the capital and killed the Zhou king, marking the end of what is known as the Western Zhou period. Thereafter China began several centuries of increasingly violent warfare, culminating in triumph of the Qin dynasty and unification of China in 221 BCE. In this era, the Chinese relied on the crossbow—a more powerful bow than was used by Greek, Persian, and early Roman armies and their opponents—and much less on swords, javelins, and battle axes.

During the Warring States period that preceded Qin unification of China, the chivalry that had supposedly hitherto characterized warfare disappeared, and, with the onset of iron weapons late in the Warring States period, armies grew larger, the role of nobles as warriors declined, and peasants figured prominently as foot soldiers. China did not rely on cavalry formations; the number of chariots one commanded was the principal indication of one's military power.

The Qin dynasty was short lived, lasting only until 206 BCE. The Qin relied on peasant armies and iron weapons to overwhelm China's foes and helped connect existing city walls to protect settled China from horsed nomads. Qin forces then began to move south of the Yangzi (Chang) River into present-day Fujian, Guangdong, and Guangxi provinces and northeast into northern Korea.

From Han to Tang

Qin's successor dynasty, the Han dynasty (206 BCE–220 CE), rivaled Rome for power, and began

The Great Wall of China, photographed here at Simatai, was built in stages between the fifth century BCE and the nineteenth century to defend China from incursions, mostly by northern steppe peoples.

a long effort to control the northern nomads—the Xiongnu—and to gain control over the lands south of the Yangzi. To meet the barbarian threat, the Han valued cavalry more than their predecessors. From 121 to 119 BCE, the Han battled the Xiongnu in western China, using more than one hundred thousand cavalry; they prevailed and gained control of profitable trade routes to the west. The Han also moved into Manchuria and took over northern Korea to the Han River. In the first century CE the Han conquered the Tarim Basin and seized Turkistan.

But then the balance of power shifted in favor of the nomadic tribes. Revolts at home weakened Chinese power, the Han lost control of Turkistan, and nomads on the frontiers penetrated Chinese defenses, terrorizing the settled peoples on the North China Plain. In 220 CE the Han collapsed and a period of disunity followed, with various regional states coexisting until China was reunited under the short-lived Sui dynasty (581–618 CE). The Sui dynasty suffered

from its attempt to do too much too soon. It pushed below the Yangzi watershed, and it attacked Korea four times without much success; that failure encouraged nomadic horsemen to attack and capture the emperor.

The Tang and Song Dynasties

The Tang dynasty ruled China from 618 to 907 CE. The Tang capital, Chang'an, was the world's largest city and attested to its great military power. Under the Tang, the Chinese first discovered and began using gunpowder, but as an explosive and not as a propellant. Curiously, this was roughly the same time that the Byzantine Empire perfected so-called Greek fire, the formula for which still eludes experts today. Tang armies continued to make use of peasant infantry and aristocratic and nomadic horsemen. At its zenith, the Tang dynasty controlled northern Korea and Manchuria, south as far as the Red River delta, west into the Tibetan lowlands, and then along the trade route toward the Caspian Sea. Four defeats in the 750s, most notably a loss to rising Arab power in the Battle of Talas River (751 CE) and the An Lushan Rebellion (755 CE), were followed by a series of increasingly costly peasant uprisings leading to a relatively rapid dynastic decline.

Once again Chinese military power faded and the nomads gained control. Frontier military commanders succeeded one another in the north, as non-Chinese nomads ruled the North China Plain. In the south, local military leaders ruled various areas. Even when the Song dynasty (960–1279) reunited much of China, its power was economic rather than military, and it relied on diplomacy and the paying of tribute to maintain peace. Nomadic groups continued to control the North China Plain. In time, the Jin, a nomadic ruling house, pushed the Song out of northern China, and from 1127 the Song controlled only the south. The Mongols overwhelmed the Jin and other northern nomads and in 1279 crushed the Song, establishing the Yuan dynasty (1279–1368) and bringing China and its periphery together under one ruling house for the first time since the Tang.

Terracotta warriors—some 8,000 of them buried underground for centuries to protect the tomb of China's first emperor, Qin Shi Huangdi—offer a glimpse into the warfare of China's past.

The Mongols and the Ming

The Mongols were the greatest military force of the era. They were a horsed people, and they emphasized mobility, with Mongol horsemen having as many as fourteen mounts each, intricate formations, a variety of feints and ruses, and absolute brutality and cruelty to achieve quick victory. The Mongols were adaptive, using techniques of conquered people in one part of their vast empire to seize control elsewhere. They took northern China, but the water-based transport, canals, and rivers of southern China stymied them until they learned how to adapt their tactics. The Mongols eventually learned to augment their limited forces (there likely were never more than two hundred thousand Mongol horsed soldiers total at any given time) with mercenaries from northern China and learned to navigate the waterways of southern China. More interested in exploiting China than in ruling it, the Mongols spent funds lavishly and weakened

themselves using Chinese and Korean troops in two failed invasions of Japan in the thirteenth century. The Mongols lacked the numbers to remain in power for long; they refused to Sinicize themselves, and the dynasty fell less than a hundred years after its establishment.

A resurgent ethnically Chinese dynasty, the Ming (1368–1644), followed the Mongols, but existed in a dangerous world. The Ming never secured control over the hinterlands and the trade routes to the northwest, where the Mongols remained a threat for many years. The Ming rebuilt the Great Wall to constrain the nomads. Later in the Ming era, Japanese ships raided the Chinese coast, and the Ming ordered the coastal population to move inland.

There was one bright moment in Ming military history, the great voyages of the eunuch admiral Zheng He. Zheng was a Mongol, whom the Chinese castrated, and he came to work for the emperor, achieving an influential position. He led a vast Chinese fleet, with twenty thousand sailors and twenty thousand marines from China, into the Indian Ocean to the east coast of Africa, greatly impressing native rulers at the same time that Henry the Navigator of Portugal was sending individual ships with perhaps a company of sailors to find a route around Africa to the east. But Zheng and sea power were passing events, and the Ming, never as powerful as the Han or Tang dynasties, weakened as Chinese officials and military experts defected to a rising power in the northeast.

The Qing

As the Ming declined, the tribal Manchus in the northeast adopted the trappings of a Chinese dynasty; in 1644 they defeated the Ming and established the Qing dynasty (1644–1911/12). Militarily, they organized themselves into companies that were known by the color of their banners (hence this system was known as the Banner system), and they incorporated conquered troops into similar units. With these troops the Qing rulers soon extended their control over the Mongols and Tibetans, and under the great Kangxi emperor (1654–1722; reigned 1661–1722) they even

All war is deception. • Sunzi (fifth century BCE)

limited Russian expansion eastward with the Treaty of Nerchinsk (1689).

The reign (1735–1796) of the Qianlong emperor (1711–1799) marked the high point of the Qing dynasty, after which it rapidly declined. Increasing Western presence in China led eventually to military conflict; two Opium wars (one with the British in 1839–1842; one with the French in 1856–1860) demonstrated the weakness of the Qing, whose Banners had lost their fighting edge and whose firearms had not been updated since they were first gained from Portuguese and Dutch traders in the 1600s. Foreign governments encroached on Chinese sovereignty with impunity. The great Taiping Rebellion (1850–1864) further exposed Qing weakness; it was only put down with aid from Western powers (the United States and the British) and privately organized Chinese armies. The so-called Boxer Rebellion (1900–1901), which had an anti-Western bent and emphasized martial arts, was also put down with international aid. In 1912 the last Qing emperor abdicated, and China became a republic, albeit one plagued by regional warlordism and foreign spheres of influence.

Wars of the Twentieth Century

Japan's imperialist visions led it to seize Manchuria in 1932; its aggression in China did not end there, however, and by 1937 the two nations were in a state of war. Equally pressing in the eyes of the Chinese Nationalists—the nominal government of China—however, were the Communist rebels. Chiang Kai-shek (1887–1975), the Nationalist leader, used German advice and equipment to blockade the Communist base camp in the mountainous southeast, and in October 1933, Mao fled with 90,000 supporters on the famous Long March first southwest, then west, north, and eventually northeast, where 8,000 survivors straggled into Yan'an in Shaanxi. At that point Chiang was reluctantly persuaded to put aside his quarrel with the Communists and to join with them to fight the Japanese.

With the end of World War II, China's civil war resumed in earnest. The Nationalists had support from

the United States, which opposed Communism, but the Communists had greater popular support and better military tacticians in Lin Biao (1907–1971?) and Zhu De (1886–1976). In accordance with Mao's theories of guerrilla warfare, the People's Liberation Army operated in small groups, seeking to overwhelm isolated detachments of larger Nationalist Army forces. Communist cadres emphasized the psychological, preparing their men and seeking to convert their enemy. In time, as Communist strength increased and Nationalist forces weakened, the Communists fought in larger units, and in 1948, large, well-armed Communist armies with more traditional tactics compelled the surrender of Chiang's best troops and won the Battle of the Huai Hai, destroying another 500,000 Nationalist troops. In April 1949 Mao's forces crossed the Yangzi River in many places, and by December 1949, Chinese Communist units had reached as far as southern China and the Vietnamese border.

Since gaining control of the mainland in 1949, the Communist rulers of China have fought only to defend what they perhaps broadly define as their interests. Worried about the intent of the U.N. forces moving to the Yalu River in October and November 1950, China intervened in the Korean War. Following attack and counterattack into April 1951, the front in Korea largely stabilized, and an armistice in July 1953 ended the outright confrontation of the People's Republic of China and the United States.

There have been border disputes with India in 1962 and in 1979 with Vietnam, and there continues to be tension over the fate of the island of Taiwan, where the Nationalists established themselves after losing the mainland. China conducted its first nuclear test in 1964, joining the ranks of the world's nuclear powers. Today the world's most populous nation and the world's third-largest nuclear power, China's military strength is sobering.

Warfare—Europe

Early Europe's military arsenal was largely connected to developments in neighboring Asia and North Africa, but changes in the structure of armed forces (e.g., the use of land-owning cavalry and knights in the eighth century) allowed Europeans to better protect themselves from marauders. Technology and training advanced weaponry, created arms races, and eventually allowed European countries to conduct warfare worldwide.

The ancient Greeks invented the idea that Europe was separate and equivalent to Asia. But a glance at the map shows that Europe is in fact a peninsula stretching westward from Asia and, as such, remains closely connected with that larger continent, while on the south the Mediterranean Sea connects it no less intimately with North Africa. Throughout the Ice Age, when glaciers covered much of northwestern Europe, and long after the glaciers began to melt away, Europe remained no more than a thinly inhabited outpost of the Asian-African heartlands. Its military history continued to depend in large part on developments in Asia until after the time of the Mongol Empire (1226–1368) and the arrival of gunpowder from China.

Innovations in Weaponry

Europe's earliest inhabitants came on foot from Africa and Asia, ferrying across the Straits of Gibraltar and the Bosphorus and Dardanelles. They were hunters and gatherers, and we know next to nothing about their warfare. Archaeologists have found a few skeletons showing wounds, inflicted either by warfare or

by hunting accidents. That is all. Agriculture arrived from Asia via the Danube Valley, and early farmers spread throughout Europe between about 8,000 and 6,700 years ago. They also possessed bows; a few rock carvings in Spain show naked archers running around and shooting at one another. Some skeletons, too, have arrows embedded in them. Early European farmers did fight one another at least occasionally, very probably in much the same disorganized fashion that Stone Age farmers in the highlands of New Guinea did when they were first discovered by the rest of the world in the 1930s.

A notable shift in military affairs came when bronze armor and weapons became available in Sumerian cities about 3000 BCE. Since the copper and tin to make bronze came from afar, only a handful of specialized warriors at first could possess these tools. Little by little bronze became more widely available, and wherever the necessary metal and specialized artisans showed up on the scene, the advantages of bronze armor and weapons were so great that warfare became the business of a small elite of professional warriors supported by rents or taxes exacted from ordinary farmers.

Bronze weapons and armor spread throughout Europe between 2800 and 1300 BCE, creating vigorous warrior elites and skilled metalworkers, sustained by far-reaching trade in metals and other objects of prestige. As early as 2800 BCE, two-wheeled chariots drawn by horses appeared on the steppe between the Ural Mountains and the Volga River; at first these clumsy vehicles were fit more for ceremony than for war. But after 1700 BCE, when strong, spoked wheels turning on a fixed axle reduced friction, and when powerful compound bows gave charioteers striking

Leonardo's fresco, *Battle of Anghiari* (1503–1505), was lost during a mid-sixteenth-century renovation of the Palazzo Vecchio. Artists' copies of the fresco, such as this one, keep the battle action (between Milan and Florence, in 1440) alive.

power at a distance and something close to invulnerability against foot soldiers, warfare was swiftly transformed throughout western Asia and Europe. Chariots were expensive and so were horses (except on the steppes), but throughout most of Europe local rulers and chieftains soon acquired the new instruments of power, even as far away as Sweden and England.

This reinforced the military and political power of narrow elites, but after about 1200 BCE the spread of cheap and abundant iron weapons made it possible for ordinary farmers to equip themselves with spears, shields, and helmets, so that tightly packed infantry, arrayed in ranks, became able to withstand chariot attacks far more successfully than before. Significant democratization of European society ensued.

Soon after 700 BCE the balance shifted once again when steppe nomads learned how to shoot their bows from horseback by letting go the reins and clinging to a galloping horse with legs alone. These tactics enhanced the mobility of steppe raiders, and their advantages over farming populations improved in subsequent centuries, most notably when someone, somewhere invented stirrups (about 200 CE) to give them a firmer seat. Finally, steppe warfare reached its apex when bureaucratic promotion on merit to command over standardized units of tens, hundreds, and thousands of men gave Mongol

armies their remarkable efficiency in the thirteenth century.

Armies and Cavalry

Keeping horses where grass did not grow naturally was always expensive and, as ancient Greeks and Romans discovered, a disciplined and armored infantry could withstand cavalry attacks as long as a sufficient number of cavalymen guarded their flanks and rear. Since Mediterranean landscapes were conspicuously short of grass and far enough from the open steppes to be safe from steppe cavalry most of the time, Greeks and Romans therefore relied mainly on armored infantry, protected by iron corselets, greaves (shin protectors), helmets, and shields. Greek hoplites, as the infantry soldiers were called, relied on spears to stab their foes face to face; Romans used swords and fought in more-open formations. At first, ordinary farmers, responsible for supplying their own equipment, filled the ranks. As long as citizen farmers dominated Greek and Roman battlefields, they had a decisive voice in war and peace and other public issues.

Democratic and republican ideals were thus implanted in the classical tradition. The idea that free men fight more bravely than subjects of royal or imperial monarchs still lingers among us. This was how the fifth century BCE historian Herodotus explained

the success of a ragged coalition of Greek city-states against the invading army of the Persian king Xerxes. But Xerxes could not feed his army through the winter and so withdrew, leaving a small garrison behind for the Greeks to defeat the next summer (the siege lasted from 480 to 479 BCE). After this triumph, citizen armies persisted in Greece until the semibarbarian king Philip of Macedon subdued the whole country, and his son, Alexander III (Alexander of Macedon, reigned 336–323 BCE) conquered the vast Persian Empire, spreading Greek influence all the way to India and initiating what historians call the Hellenistic era.

The Macedonian army relied on infantrymen equipped with far longer spears than the Greeks had used, supplemented by far larger bodies of cavalry than the Greeks had been able to afford. The combination of a hedgehog of moving spears driving back the foe supplemented by headlong cavalry attack on vulnerable places in the enemy front proved irresistible on the open ground. Alexander's soldiers also overcame even elaborate fortifications by a combination of massive earthworks and scaling ladders. For the first time, a European army clearly excelled its Asian rivals, but the advantage was transitory.

To be sure, the Romans conquered the shores of the Mediterranean Sea, overthrowing the Hellenistic kingdoms with ease, and penetrated Europe as far north as England and the Rhine and Danube rivers. But Persian rulers retained control of the Tigris-Euphrates Valley most of the time despite Roman invasions. Persian success against Roman armies rested principally on the fact that they had developed a large and powerful breed of horses that were capable of carrying fully armored men on their backs. Such beasts needed abundant fodder, but by planting alfalfa on fallowed fields, the Persians assured themselves of sufficient fodder with no diminution of grain harvests, since alfalfa crowded out weeds as effectively as summer plowing could, and also formed nitrogenous nodules on its roots to fertilize next year's grain.

The Persians' heavy-armored cavalry, equipped with powerful bows, resembled old-time chariots in being able to harass and defeat infantry almost with impunity, hence Roman failures. But the big horses

also could meet steppe cavalry raiders on more or less even terms, protecting local farmers even if they could not pursue steppe ponies very far across the steppes since natural grass was too scant to feed them adequately.

Not surprisingly, the Romans and even a distant Chinese emperor set out to import big horses from Persia in hope of acquiring such a formidable cavalry force for themselves. Yet the big horses were so costly to feed that they never became numerous in China and eventually disappeared. In Europe, however, the Persian style of armored cavalry, introduced under Emperor Hadrian (reigned 117–138 CE), became the backbone of the East Roman or Byzantine army by the time of Justinian (reigned 527–565 CE). But unlike the Persians, the Romans paid these fighting men in money, realizing that central control would falter if they scattered out across the landscape and began to live on private estates.

Knights

Soldiers in western Europe began living on private estates after the Frankish ruler Charles Martel introduced the new style of cavalry in 732 CE by granting land to men, later called knights, in return for promises of military service. For a long time, Western knights remained very few and, unlike their counterparts further east, relied on spears to bring decisive force against their enemies. By the time they became common, the Western Roman Empire was long gone, and German invaders had set up rival kingdoms. Although Charlemagne crowned himself Roman Emperor in 800 after subduing mainland Europe from the Pyrenees to the Hungarian plain, his successors split his empire into rival kingdoms once more. They miserably failed to safeguard their subjects from fresh waves of attackers—Vikings from the north, Arabs from the south, and Magyars from the east.

Local self-defense was urgent, and the means to support it came onstream when the use of heavy moldboard plows drained waterlogged landscapes, converting them to fertile fields. Knights adequately supported by this new sort of agriculture multiplied accordingly, and eventually became thick enough on

the ground to repel foreign raiders. Thereupon, effective local protection assured population growth. From about 1000 to 1300 CE, western Europe became a prosperous frontier land as forests became fields on a massive scale, and all the skills of civilization began to flourish across the north European plain for the first time.

Knightly warfare proved so effective that it expanded in every direction from northwestern France and Germany where it first arose. Knighthood reached England in 1066 with the Norman Conquest; knights had earlier begun to reconquer Spain from Muslim rulers—a process completed only in 1492. The main area of expansion lay eastward where a moving frontier of settlement carried German knights across the Elbe River and eastward to the climatic limits within which moldboard farming was feasible. A new medieval civilization took shape during these same centuries, and western Europe swiftly caught up with its neighbors in military matters—a fact registered by the initial success of crusaders who carried European arms all the way to Jerusalem in 1099 and remained there until 1187.

Arms Races

The Mongol armies that brought steppe warfare to its apex and overran most of Asia before conquering Russia in 1240 never penetrated the rest of Europe. But under the Mongol Empire (1226–1368), trade and travel across Asia intensified, and familiarity with gunpowder (as well as with printing and the compass) reached Europe from China, transmitted by anonymous artisans. The Chinese began to experiment with guns about 1290, but the earliest certain evidence of gun making dates from 1326 in Europe and 1332 in China, taking the form of two drawings of very similar vase-shaped vessels with an oversized arrow projecting from their mouths.

Long before gunpowder upset older ways of warfare, however, European knights suffered unexpected defeat at the hands of pike-carrying Italian foot soldiers in 1176; and when cities like Genoa began to manufacture powerful steel crossbows (initially used to defend ships at sea), knights lost their easy

supremacy on land. Rival cities in northern Italy responded by pioneering the management of mercenary armies composed of crossbowmen, pikemen, and cavalry, while innumerable Italian artisans launched an arms race between ever stronger and nimbler crossbows and more perfect armor.

When gunpowder reached Europe, it had immediate and very drastic effects on warfare, whereas in China and other parts of Asia its effects were much less. That is not really surprising, since where cavalry warfare prevailed, early guns were useless for men on horseback; in China the government relied on walls to resist raiders from the steppes, and crossbows defended such walls more cheaply and far better than early guns could do.

But in Europe kings were interested in anything that could breach town and castle walls and allow them to assert their authority more firmly. Moreover, European artisans already knew how to cast church bells and speedily used the same skills for casting bigger and bigger guns. Not surprisingly, European guns quickly outstripped what Chinese and other Asian artisans produced—a lead that Europeans retained for centuries, at the cost of suffering increasingly destructive wars among a shifting array of growingly powerful states.

The Italians dropped out of the new arms race, which centered in the borderlands between France and Germany where French kings and German emperors competed for the best and newest guns. The speed was astonishing with which the toylike vase gun of 1326 was transmuted into clumsy bombards, about 3.5–4.5 meters (12–15 feet) long, like those that breached the walls of Constantinople in 1453. By 1477, they were replaced by mobile guns, about 2- to 2.5-meters (6–8 feet) long, permanently mounted on wheels yet capable of destroying city and castle walls in a few hours by shooting iron cannonballs.

Monarchs throughout Europe hastened to buy these weapons and used them to overawe rivals at home and expand their power to neighboring lands. Though dwarfed by the new style of armament, Italian city-states were not baffled for long by the power of the new siege guns. Instead, in 1500 the Florentines discovered almost by accident that loosely compacted

F. Oettinger, *European Cavalry Battle Scene* (1785). This gouache painting depicts a violent cavalry battle during the Seven Years' War (1756–1763), a conflict that involved all the major European powers and became known as the first global war.

earth could absorb cannon shot harmlessly, and by digging a vertical hole in front of earthen ramparts, attackers had to cross what amounted to an inverted wall in the face of defending guns. This so-called *trace italienne* put an effective obstacle in the path of Europe's imperial unification of the kind that came to Russia, Turkey, India, and Japan when mobile siege guns like those of Europe reached those lands. But the new fortifications were expensive to construct, and thousands of guns defending (and attacking) them remained essential for enhancing royal power.

Worldwide Warfare

Another significant military change resulted after 1514 when King Henry VIII of England put cannon on board a specially designed warship that had gun ports near the waterline to assure stability. Such ships could deliver a devastating broadside to more lightly armed vessels. Within a single generation (1492–1522), when advances in navigation and knowledge of ocean winds and currents allowed Europeans to sail across the oceans, cannon-carrying ships were available to support their presence on all the coastlines of the Earth. Subsequent conquest and settlement of the Americas depended both on gunpowder weapons and on the infectious diseases Europeans brought with them that proved deadly among previously isolated populations.

In the short run, Spain was the state that profited most conspicuously from the discovery of the Americas. A handful of Spaniards conquered first Mexico and then Peru between 1521 and 1533, and rich silver mines soon supplied King Philip I of Spain (reigned 1556–1598) with a flow of silver that allowed him to more than double the size of his army. Despite American silver, paying so many soldiers and sailors drained the treasury, and three successive bankruptcies paralyzed King Philip's hopes and plans. Mercenary soldiers had dominated the scene in Italy for two centuries by King Philip's time (where he ruled Milan, Naples, and Sicily), when money and credit had become essential for paying and equipping armies throughout Europe. Even the greatest of kings found themselves entangled in debts owed to merchants and bankers.

Under the circumstances, states that managed to increase taxes and repay loans on time fared better than those where royal and aristocratic disdain of money prevailed, as in Spain. The Dutch led the way. They also developed new forms of drill, discipline, and command that made their armies efficient as never before. Maurice of Nassau, Prince of Orange and captain general of Holland and Zeeland between 1585 and 1625, set out to match ancient Roman armies by drilling his soldiers for long hours whenever they were not fighting, marching, or digging trenches for a siege. Endless practice of marching and going through

the motions needed to load and fire muskets in unison and in obedience to shouted commands made firing quicker and more reliable in battle.

Moreover, prolonged rhythmic movements—a sort of dance—aroused feelings of solidarity and togetherness that made well-drilled soldiers willing and able to stand fast even when enemy bullets were flying among them. Maurice's drill spread very fast to other European armies; for the next two hundred years European soldiers, recruited among poor peasants and drifters on city streets, nevertheless obeyed their officers with superior precision and effectiveness wherever they found themselves. These mercenary armies employed young men who might otherwise have been poor and riotous subjects, yet in uniform and under military discipline upheld peace and order even against their like at home. It was they who established Dutch, French, and English empires overseas and extended the Russian Empire southward and eastward overland.

Within western Europe, each army was so nearly matched with its neighbors that an unstable balance of power was maintained. But on the margins, whether in Ireland, America, Siberia, or India, systematic expansion set in. Europe, in short, launched itself on a self-reinforcing cycle whereby military organization sustained and was sustained by economic and political expansion at the expense of other peoples of the Earth.

The Seven Years' War (1756–1763) came close to being a world war, fought, as it was, in Europe, America, and India. Great Britain decisively defeated the French in America and India, while in Europe, Prussia survived against overwhelming odds, thanks to Prussian armies, British subsidies, and potatoes, a crop recently introduced by Frederick the Great (reigned 1740–1786). Potatoes kept his soldiers and subjects alive year after year as Russian, French, and Austrian armies marched to and fro across the Prussian landscape, confiscating grain to feed themselves everywhere they went.

Prussia's survival provoked other Europeans to propagate potatoes in fallow fields wherever they would flourish; British successes overseas provoked the French to improve their field artillery by careful scientific experiment and to build a larger navy with which to challenge Britain anew. When British

efforts to tax their American colonies to help pay for the Seven Years' War aroused armed rebellion, the French seized the chance to revenge themselves in 1778 by supporting the Americans' Revolutionary War. Subsequent French victories at sea, together with French and American troops on the ground, finally compelled the British army to surrender at Yorktown, Virginia, in 1781.

But the French government had difficulty paying for their victory, and when it summoned the Estates General in 1789 to raise new taxes, simmering discontent and admiration for the republican government inaugurated in the United States of America two years before suddenly boiled over into a revolution that soon convulsed all of Europe until 1815. Population pressure had been mounting within most of Europe for a generation or longer, and this contributed to popular discontent, while appeals to reason, centered especially in France, had challenged exemptions from taxation and other privileges that nobles and priests enjoyed. When elected representatives deposed and executed the French king and queen in 1793, other Europeans were shocked. Warfare, commenced in 1792, swiftly intensified when the revolutionary government declared a *levée en masse* whereby all males capable of bearing arms were summoned to fight the invading armies.

The *levée en masse* supplied French armies with an unprecedented number of recruits, and revolutionary enthusiasm, expressed in the slogan "Liberty, Equality, Fraternity," together with enormous efforts to train and equip them with weapons, began to pay off in 1794 with victories against Prussian, Austrian, and British invaders. The advancing French were soon overrunning Belgium, Germany, and Italy, where local populations sometimes welcomed them as liberators.

For the next twenty years, most of Europe was at war save for brief interludes. Varying coalitions of Britain, Austria, Prussia, and Russia together with lesser states struggled against the French and their allies and/or subjects in newly annexed parts of the continent. Political infighting in Paris brought a successful general, Napoleon Bonaparte, to power in 1799; he crowned himself emperor of the French five

years later. Armies became far larger than before, and artillery, now light enough to keep up with marching infantry, played a bigger role in battle than before. Yet thanks largely to potatoes, peasants did not starve as they had in the Thirty Years' War (1618–1648). Peace, when it came after Napoleon's final overthrow and exile in 1815, left Europeans no poorer and militarily far more powerful than they had been in 1789.

Industrialization

The relative peace and prosperity in Europe was due to fact that war had accelerated the manufacture both of armaments and of other branches of industry. More and cheaper goods that were produced by new machinery using both waterpower and steam engines generated new wealth, new markets overseas, and new jobs for growing populations. Britain, Belgium, and Germany, where coal abounded, soon outstripped France, where coal was scarce.

As for military affairs, for a generation after 1815 European governments tried to maintain peace, and armies and navies remained content with the way things were. That began to alter in the 1830s when the French adopted guns designed to fire shells that exploded on impact and could destroy wooden warships with ease. Change accelerated after 1840 when the French and British navies and the Prussian army all abandoned the weapons that had served their

predecessors so well, and a general arms race got under way. The two navies shifted first to iron and then to steel ships powered by steam and armed with larger and larger breech-loading guns, while the Prussian army invested in breech-loading rifles, making older infantry tactics obsolete. Then, when Britain and France joined forces against the Russians in the Crimean War (1854–1856), traditional artisan methods of shaping metal by hand proved utterly inadequate to turn out new rifled handguns. The British responded by borrowing American methods of using semiautomatic machine tools to turn out standardized parts in hitherto unimagined quantity. Mass production quickly spread to the arms makers of all Europe.

Simultaneously, mechanized transport—railroads and steamships—enlarged transport capabilities, and the American Civil War (1861–1865) showed Europeans how armies of enormous size could be supplied from far in the rear for months on end. Mechanized transport also allowed the British navy to compel China to open its ports to the opium trade (1839–1842) and soon afterward Americans induced Japan to open itself to the rest of world (1854). And all the while the British and the French led the way in expanding European empires in Africa and Asia.

Within Europe itself, however, the state that most profited from the mechanization of warfare was Prussia. The General Staff had a decisive voice in

Parisians rallied in support of France during the Franco-Prussian War (1870–1871) crying out, “Vive la guerre!” (Long live the war!)

determining exactly how Prussian railways were laid out, and then it made detailed plans for using the railways to deliver the maximum number of men and equipment to the frontiers in minimal time. Their careful planning paid off when war broke out, first with Austria (1866), then with France (1870–1871), leading in both cases to quick Prussian victories. Thereupon, nationalists who had long yearned to unite the separate German states formed the new German Empire under Prussia's lead.

In the next half century, the arms race intensified. Battleships became larger and faster, armed with enormous steel guns capable of projecting heavy shells as much as 32 kilometers (about 20 miles). Design of field artillery for land warfare improved almost as much, with faster fire, better sights, and greater mobility. New weapons also threatened existing ways of war as airplanes, submarines, and torpedoes extended their reach above the Earth and beneath the sea.

Twentieth-Century Warfare

The long-standing French–British rivalry subsided after Emperor Wilhelm II (reigned 1888–1918) came to the German throne and decided to seek world power by building a navy to rival that of the British.

Simultaneously, German army planners began to fear that new Russian railroads might allow Russia's superiority in numbers to endanger their eastern frontier. The result was that after 1907 a triple alliance of Germany, Austria, and Italy confronted the Triple Entente of France, Britain, and Russia.

World War I and Its Aftermath

This was the situation that precipitated World War I (1914–1918). Assassination of the heir to the Austrian throne by Serbian revolutionaries was the spark that set it off, and Austrian plans to retaliate by invading Serbia provoked Russian mobilization, whereupon German and French armies also mobilized. Once mobilization got under way, no one dared to back down and risk unreadiness in the face of the enemy. Britain hesitated, but German invasion of the neutral Belgium on 4 August 1914 persuaded the British to join its allies and hurriedly dispatch a small army to France. Unlike the continental powers, however, the British army had few reserves, so its full military effort was delayed until 1916 when civilian volunteers (later conscripts) had been equipped, trained, and sent abroad to join the struggle.

The German mobilization plan proved initially to be the most successful. As in 1870, it aimed at

A pre-World War I German howitzer and shield. By the beginning of the twentieth century, design of field artillery for land warfare improved, with faster fire, better sights, and greater mobility.

defeating the French quickly by marching seven armies across Belgium. But after weeks of strenuous marching, a gap opened between their armies, and a desperate French effort halted the German advance at the River Marne. Very quickly improvised trenches sheltered soldiers on both sides from enemy fire, and within a few months trenches stretched all the way from the Swiss border to the North Sea. For the next four years repeated efforts to break through ever-more-complicated defenses failed to do more than shift the front by a few kilometers.

In the next four years, other states, as near as the Ottoman Empire and as far away as Japan, joined one side or the other, turning the conflict into World War I. In addition, mobilizing the home front to assure adequate war supplies transformed civil society, especially in Europe, as government officials, big business, and big unions collaborated to enlarge the output of munitions while rationing food and other civilian consumption. Welfare and warfare intermingled, since a healthy and contented workforce was essential to the war effort. When welfare wavered as food shortages set in, first Russia and then Germany would eventually have to stop fighting.

Shortages of coal and iron ore in France required purchases abroad from the start; both Britain and France imported grain, cotton, and manufactured goods from the United States in growing quantities. American bankers were soon making loans to finance such imports. Other purchases of food and raw materials from Asia, Africa, South America, and the islands of the sea also swept those lands into a transgovernmental, flow-through, managed economy designed to maximize the power of Allied armies. Germany and its allies did the same but on a lesser scale, since the British navy blockaded Germany in the North Sea and intercepted imports whenever it could.

The eastern front was always too lengthy to settle down to trench warfare, but there, too, neither side could win until shortages of food and ammunition began to cripple the Russians. Communist revolutionaries in Russia took power in November 1917 and made peace by ceding the Ukraine and other territories to Germany in March 1918. The fact that the United

States declared war against Germany in April 1917 more than compensated for this temporary German victory. More than a million American soldiers arrived in France by the time reinforcements from the east allowed the Germans to mount a final offensive. It met initial successes, but the French and British held and, with the help of American troops, reversed the tide of battle as growing shortages of food and ammunition weakened the Germans. On 10 November 1918 an armistice signified the Allied victory a few days after socialists had seized power in Berlin. By then, about 10 million men had been killed in battle, and drastic economic disruption and enormous war debts threatened to paralyze Europe's future.

Across the next four years, peace was defined by a series of treaties. The victors sought to ensure themselves against German revenge by transferring marginal territories to neighboring states, demilitarizing the Rhineland, limiting the German army to 100,000 men, and more generally by organizing the League of Nations to keep the peace. Still more American loans were necessary before economic recovery came to Germany, soon followed by a New York stock market crash in October 1929 and years of deep, worldwide depression.

Widespread unemployment provoked a radical response in Germany, where Adolf Hitler brought his Nazi Party to power in January 1933, and in the United States, where Franklin Roosevelt proclaimed the New Deal three months afterward. In both countries, expanded government expenditures on roads and other public works did something to diminish unemployment, but the Depression ended only when wholesale rearmament, first in Germany, then more reluctantly in Britain, France, and the United States, prepared the way for World War II. Japan also militarized its economy beginning as early as 1931, when they invaded Manchuria and then attacked China in 1936.

World War II

In Europe, Hitler proclaimed the superiority of the Aryan race, blamed Jews and Marxists for Germany's defeat in 1918, and set out to undo that defeat by propaganda, diplomacy, and, if need be, by war. At

European merchants supply the best weaponry, contributing to their own defeat. • **Saladin (c. 1137–1193)**

first, France and Britain caved in, abandoning Austria and then Czechoslovakia to Germany in 1938; when Hitler made a surprising agreement with the Soviet Union (formerly Russia) and invaded Poland in September 1939, the French and British reluctantly went to war once more. This time, German war plans proved more successful, defeating Poland in 1939, France in 1940, and occupying Norway, Denmark, and the Low Countries (Belgium, the Netherlands, and Luxembourg) as well as the Balkans. But bombing London failed to persuade the British to surrender, and the British navy frustrated plans for a cross-channel assault, so in 1941 Hitler decided to attack the Soviet Union instead, expecting another swift and easy victory.

The initial attack carried German tanks and mechanized infantry deep into the Soviet Union, besieging Leningrad and reaching the outskirts of Moscow by December 1941. Winter cold and supply shortages then forced German armies to a halt exactly when a Japanese naval attack on Hawaii's Pearl Harbor brought Americans into the war. Roosevelt had already aided Britain short of joining the war, and Hitler reacted to the news of Pearl Harbor by gratuitously declaring war on the United States. He thus relieved President Roosevelt of what might have been an insurmountable obstacle to following his preferred strategy of defeating Germany first, on the ground that Hitler's power was more threatening than anything the Japanese could offer.

From then on the course of the war depended very largely on the flow of supplies of every kind from farms and factories to battlefields scattered all the way from the Solomon Islands in the southwest Pacific to Stalingrad on the Volga River, and from Alaska to Burma. The Germans never really integrated their war plans with the Japanese. Transport was too difficult, and trust was scant. The Anglo-Americans did far better, establishing joint commands and concerting economic and strategic plans more efficiently than had been done in World War I. Soviet armies benefited from food and trucks that reached them from America, although trust between the Soviet leader Joseph Stalin and the Anglo-

Americans was never firm. And the Soviet Union, like France in World War I, manufactured nearly all the tanks, artillery, and airplanes the Red Army needed to drive the Germans back, beginning with a successful counterattack at Stalingrad in September 1942 and breaking the Leningrad siege in January 1943. A little earlier, the Battle of Midway (June 1942) turned the tide in the Pacific.

Hard fighting continued until 1945, involving massive air attacks on Germany, a successful Anglo-American cross-channel invasion in 1944, and continued Soviet advances all the way to Berlin. With defeat certain, Hitler committed suicide on 30 April 1945, leaving others to surrender in the early days of May. The Japanese fought on, as American forces advanced across the Pacific, but finally surrendered after American airplanes dropped atomic bombs over Hiroshima and Nagasaki in August. Formal surrender on 2 September 1945 ended a struggle that resulted in about 22–25 million military casualties and the deaths of approximately 40–52 million civilians, including nearly 6 million Jews, the victims of the Holocaust. (Such unprecedented numbers, although they are still subject to historical research in the twenty-first century, reflect a dramatic and disturbing shift in the tactics of world powers that continues to resonate among us: the blatant targeting of civilian populations, whether by strategic bombing, population transfers, or persecution.)

Outlook in the Atomic Age

The atomic bomb was the most spectacular and frightening technology to emerge from World War II. Fear of seeing atomic clouds like those that towered over Hiroshima and Nagasaki have haunted international politics ever since. Innumerable other new devices—radar, proximity fuses, guided missiles, rockets, jet engines, and computers, to name only the most significant—also affected military, political, and civilian life during the war itself and thereafter.

When surviving Jews established the State of Israel in 1948 and forcibly expelled many thousands

of Palestinians, they aroused intense resentment among Muslims in general and Arabs in particular. Subsequent brief local wars favored Israel, with the help of arms and money coming mainly from the United States. And when Muslims resorted to acts of terrorism not only against Israel, but also against the United States (September 11, 2001), President George W. Bush (in office 2001–2009) declared the War on Terrorism, which reached the nine-year mark in 2010 with no end in sight. American forces invaded Afghanistan without eradicating all the terrorists who had found shelter there, then attacked Iraq and easily overthrew Saddam Hussein (1937–2006) only to provoke years of violence. Many people believe that as long as the United States supplies the Israeli armed forces with modern weapons and tolerates Israeli attacks on Palestinians and the sporadic establishment of new settlements on Palestinian land, then it seems certain that thousands of angry Muslims will continue to plan terroristic acts, often sacrificing their own lives in order to kill Israelis, Americans, and also Europeans.

Such terrorism may become a running sore, but fears of atomic disaster have so far remained no more than a bad dream. Even after the aptly nicknamed Cold War broke out between the United States and the Soviet Union, and the Soviets tested their first atomic warhead (1949), actual atomic attack failed to materialize. In the course of the next half century or so, other states—Britain, France, Israel, China, India, and Pakistan—also acquired atomic capabilities, yet none of them has yet employed an atomic warhead against an enemy. Nor have any of these governments ever approached the number of U.S. and Russian warheads and rockets poised and ready to deliver them anywhere on Earth.

Eventually, in 1991, Communist mismanagement of production, both for war and peace, provoked the swift and surprising dismantlement of the Soviet Union. Satellite Communist regimes in Eastern Europe also foundered, and a shaky balance of power between the new Russia and the rest of the world emerged. That tended to destabilize the atomic stand-off since the Russians became unable to guard all

their atomic installations as before. A similar meltdown in Pakistan, should it ever occur, would be far more dangerous since Muslim terrorists already abound within Pakistan's borders. As of 2010, terrorists had not acquired the fearful capability of atomic weaponry, though the threat remains for the foreseeable future.

Although an isolated explosion could be horrific, the fact remains that it is the great powers with large arsenals of warheads that may destroy human life on Earth if they ever launch an all-out assault on one another. The Russians, Americans, Chinese, and Indians have so far refrained. If that continues, humankind may yet survive despite our long-standing propensity and mounting capability for killing as many enemies as possible in times of war.

Warfare—Islamic World

Military conquest was important in the spread of Islam. Within twenty years after the death of Muhammad much of the Middle East had been conquered; within one hundred years Islam stretched from Spain to India. Muslim armies, fortified by gunpowder, professional armies, and revolutionary military techniques and tactics, experienced overwhelming global success until the nineteenth century.

The spread of Islam and the conquests of Muslim armies in the decades that followed the death of the Prophet Muhammad in 632 CE were events of world historical significance that have had far-reaching consequences down to our own time. By 650 CE, Palestine, Syria, Egypt, Iraq, and Iran had been conquered. Under the Umayyad dynasty (661–750 CE) the Islamic caliphate stretched from Spain in the west to India in the east and from southern Arabia to Central Asia. Although the caliphate dissolved into many Muslim states as early as the eighth century, Islam continued to spread among new peoples, including the Turks and the Persians, who both were to play major roles in Islamic history. Although no Muslim state existed in Spain by the sixteenth century, Islam made new advances in the Balkans and central Europe under the Ottoman Turks (c. 1300–1922). Of the major sixteenth-century Islamic empires, the Ottomans controlled parts of Hungary, the Balkans, Anatolia, and most of the Middle East, the Safavids (1501–1722/1736) ruled over Persia and parts of Iraq and Afghanistan, and the Mughals (1526–1857) conquered much of India. Although military conquest was important in the spread of Islam, in territories outside the effective radius of Muslim armies, such

as the Indonesian archipelago, the Malay Peninsula, and parts of Africa, mass conversion was achieved via merchants and missionaries, making the spread of Islam in those regions a cultural rather than a military advance.

Expansion of Islam

Historians have tried to explain the remarkably swift and enduring Muslim conquests in many ways. Some have stressed the relative weakness of their opponents; others have stressed the effects of the plague or the power of the new religion (Islam) and ideology (jihad). Still others have emphasized the personal qualities of the first caliphs, the Ottoman sultans, and the founders of the Safavid and Mughal empires, as well as the valor of Muslim fighters. To this long list we should add the ability of Muslim rulers to establish professional armies and effective state bureaucracies and financial organizations.

Building on the foundations of ‘Umar ibn al-Khattab (reigned 634–644), the caliph who established the first garrison towns and the first registers of the names and salaries of the troops, the Umayyads completed the transformation of a tribal migration into a professional army. Around 700 CE, the soldiers in the garrison cities throughout the caliphate might have numbered some 250,000 men. The soldiers were paid in minted coins and supported by an efficient logistical system and bureaucracy.

Starting in the 830s, the Abbasid dynasty (749/750–1258) began to recruit Turkish-speaking mounted archers from Central Asia, predominantly as slave soldiers. Though only a couple of thousand in number, their new military technique (mounted

Miniature depiction of the Battle of Ain Jalut in 1260 CE, during which the Mongols, led by Chinggis Khan's grandson Hülegü, were defeated by the Egyptian Mamluks. German National Library.

archery), tactics (feigned retreat), skills in horsemanship, and superior horses added considerably to Muslim armies' speed, maneuverability, and firepower. Soon, most Muslim armies were dominated by Turkish soldiers.

The military slave system not only revolutionized Muslim warfare, it also had far-reaching political consequences. Recruited from among outsiders with no "political baggage" and entirely dependent on the state for its subsistence, the slave soldiers were a loyal and effective force. Isolated from the rest of the society, however, their main concern was to preserve their status by dominating the government and policy. This led to the Abbasids' loss of control over their empire and the emergence of local dynasties and military dictatorships as well as to bitter wars among competing dynasties.

In the west, the Spanish Umayyads (756–1031), Almorhads (1130–1269), and the Nasrids (1230–1492) not only held on to their conquests for shorter or longer periods in Spain, they also established flourishing

cultural centers (Cordova, Seville, Granada). In the east, the Turkish Ghaznavids of Afghanistan (977–1187) spread Islam to the Punjab, laying the foundations of the religious division of the Indo-Afghan frontier, the latest consequences of which have been the creation of Pakistan in 1947 and the conflict between Pakistan and predominantly Hindu India.

In the wars within Islam, the division between Sunni and Shi'a Muslims played a crucial role. The Shi'a Buyids (c. 945–1055) and Fatimids (909–1171) launched several campaigns against their Sunni rivals. The Buyids' rule was ended by the Sunni Seljuks (1038–1157), while the Fatimid Empire was extinguished by Saladin (1137/38–1193), the founder of the Ayyubids of Egypt (1169–1252). Saladin also distinguished himself against the crusaders, defeating them in the battle of Hattin (1187) and recapturing Jerusalem, Islam's third-holiest place.

Of the conflicts with non-Muslims, the Mongol invasion in the 1250s had far greater impact on the history of the Islamic heartlands than the crusades. In 1258 Hülegü, Chinggis (Genghis) Khan's grandson, eliminated the last vestiges of the Abbasid caliphate. However, in 1260 the Mongols were defeated in Syria and driven back by the Mamluks of Egypt. The Mamluk sultanate (1250–1517) was the most sophisticated of the military states set up by Turkish slave soldiers in the Middle East, with a mobilizable professional cavalry numbering between forty thousand and seventy thousand in the late thirteenth century.

The experience of the various Islamic states with firearms varied greatly, and the nature, success, or failure of this experience depended on historical, social, economic, and cultural factors rather than on religion. The Ottomans were especially successful in integrating gunpowder technology into their land forces and navy. Preceding their Muslim and Christian rivals, in the fifteenth century the Ottomans set up permanent troops specialized in the manufacturing and handling of firearms: artillerymen, armorers, bombardiers, grenadiers, and the Janissaries, the sultan's elite slave soldiers, recruited through the child levy from among the empire's Christian population. The Ottomans also established a robust arms

My Palestinian intellectual friend tells me that he might be willing to admit that God in Hebrew said Jews could have Israel. But he said Allah did not speak it in Arabic to the Arabs. • Arthur Hertzberg (b. 1921)

industry that made their empire largely self-sufficient in weapons and ammunition until the mid-eighteenth century. Favorable geopolitical location, ample resources, efficient central and provincial bureaucracy, talented statesmen, well-trained and well-equipped professional soldiers, and superior logistics made the Ottoman army—with deployable troop strength of eighty to one hundred thousand—a formidable force.

Before the Nineteenth Century

Eurocentric narratives of Islamic history concentrate on the clash between Crescent and Cross, as well as on the supposed superiority of the “West.” But wars within Islam and against non-Muslim enemies other than Christians were equally important. Similarly, the triumph of the West is largely a phenomenon of the nineteenth and twentieth centuries, and to project that triumph back into earlier centuries is anachronistic.

While the Ottomans devoted considerable resources to their wars against their Christian opponents (Byzantium, Venice, Hungary, Habsburg Spain and Austria, Portugal, and Russia), they also absorbed a dozen or so Turkish-Muslim principalities in Anatolia (fourteenth and fifteenth centuries), were defeated by Timur (1402), destroyed the Mamluk sultanate (1516–1517), and fought countless and exhausting wars against their Safavid Shi’a neighbor, Persia.

For the Safavids, not Portuguese imperialism, but the Ottomans, the Mughals, and the Shaybanid Uzbeks of Transoxania were the major threat. Safavid rule was ended by the Ghilzai Afghans of Kandahar in 1722. The Afghans in turn were overthrown by Nadir Shah (1736–1747), an able Turkmen general from Khorasan. Nadir waged wars against Persia’s traditional enemies, the Ottomans and Mughals.

When Muslim and Christian armies clashed in the sixteenth and seventeenth centuries, the Muslims usually had the upper hand. All this changed in the late eighteenth century. Russian success against the Ottomans (1768–1774, 1783, 1787–1791) and Napoleon’s invasion of Egypt (1798) signaled the shift in power between Islam and the West.

The Long Nineteenth Century

In response to European expansion, nineteenth-century Muslim rulers attempted to modernize their armies along European lines. While initial reforms concentrated on the technical aspects of warfare and thus brought only limited results, the destruction of the Janissaries by Sultan Mahmud II (reigned 1808–1839); the introduction of conscription by Muhammad Ali of Egypt (reigned 1805–1848) in the 1820s and by the Ottomans in 1838; and the establishment of military and naval academies and schools, staff colleges, and war ministries in Egypt and the Ottoman Empire were more significant reforms. Modernized Egyptian and Ottoman armies were successful against local guerrilla forces and insurrections, but were defeated by the combined forces of nationalism and Great Power imperialism. France occupied Algeria in 1830, while Britain occupied Egypt in 1882, chiefly to control the Suez Canal. Due to Great Power intervention, a series of national states were carved out in the Ottoman Balkans, and by 1878 Istanbul had lost most of the peninsula. But thanks to improved administration and communication made possible by the railway and the telegraph, the Ottomans not only kept Anatolia and the Arab lands, but under Abdülhamid II (reigned 1876–1908) they asserted firmer control over these lands.

During the nineteenth century, warfare also became more destructive for noncombatants. Serbian, Bulgarian, Greek, and Armenian Christian rebels, insurgents, and guerrilla forces, often with Russian support, killed Muslim civilians in the Balkans and Anatolia. Ottoman irregulars, often composed of recently arrived Muslim refugees expelled from Russian-conquered lands, and the regular Ottoman army retaliated with ferocity. About 600,000 Armenians perished in the Armenian massacres of 1915–1916 alone, while the number of Ottoman Muslim victims—those who perished or were killed or expelled from territories occupied by Christians—between 1821 and 1922 is estimated at about 10 million.

The military came to play an important role in politics. In the Ottoman Empire, the coup of the “Young

Turk” officers restored the constitution and left the government in civilian hands until 1913, when a military dictatorship took over. When the empire was defeated, occupied, and truncated by the victors of World War I, another Young Turk officer, Mustafa Kemal (Atatürk), led a successful war of liberation and created a secular nation-state, the Turkish republic. In Persia, Reza Khan, the leader of a Cossack brigade, seized power in 1921 and proclaimed himself Shah in 1925, ending the rule of the Qajars (1794–1925) and establishing the Pahlavi dynasty that ruled Iran until the 1979 Islamic revolution.

The Twentieth Century

From the end of World War II until the Suez Crisis in 1956, Britain and France dominated the heartlands of Islam. By creating states with artificial boundaries, they planted the seeds of future border disputes and wars (including, for example, Iraq’s invasion of Kuwait in 1990). The creation of Israel in 1948 and the first Arab-Israeli war had profound consequences for the future. For the victorious Jews it seemed that war and land grab rather than negotiations was the effective way to deal with the Arabs. For the Palestinians, of whom 700,000 became refugees, the war sent a similarly erroneous message: if they were to regain their homeland, they had to destroy the Jewish state, a policy abandoned only in 1988 when the PLO issued a call for a Palestinian state to coexist with Israel.

The Israeli-Arab conflict has involved various forms of organized violence. There have been atrocities and terror committed by both sides: open wars (1948, 1956, 1967, and 1973); Israeli military occupation of the West Bank and Gaza since 1967; Israeli invasion of Lebanon in 1982; unarmed Palestinian uprising; armed insurrection and guerrilla war against Israeli occupation; Palestinian assassinations and suicide bombers targeting Israeli soldiers, settlers, and civilians; Israeli-targeted assassinations of leaders of Palestinian military, paramilitary, and political organizations thought to be responsible for attacks on Israel; and punitive demolition of homes of Palestinian militants, terrorists, and their relatives.

The superpowers were soon involved in the region, for economic reasons such as oil and political reasons such as containing Communism or imperialism (depending on the superpower). Instead of becoming directly involved militarily, the superpowers tried to tip the balance of power by arming their clients. The ensuing arms race made wars very destructive. In the Iraq-Iran war, in which Iraq’s use of chemical weapons outraged the world, some 1.5 million perished. Revolutions and military coups of various types also plagued the region.

The collapse of the Soviet Union left the United States as the sole superpower. The United States has established several military bases in Turkey, Saudi Arabia, Qatar, Bahrain, and Kuwait. Its role in the first Gulf War, its treatment of Iraq in the following ten years, and its strategic partnership with and support for Israel in the Israeli-Palestine conflict has fueled rage against the United States throughout the Muslim world. Anti-Americanism has been exploited by militant Islamist extremists whose terrorist attacks have targeted the United States and its allies, reminding the world that even the militarily most sophisticated and economically strongest societies are vulnerable. Continuing resistance to the United States and the U.S.-backed governments in Iraq and Afghanistan has shown the limits of Western armies in asymmetrical warfare.

On September 11, 2001, followers of Osama bin Laden, then based in Afghanistan, hijacked

four civilian airplanes and flew two of them into the World Trade Center “twin towers,” landmark skyscrapers in New York that both burned to the ground; the third plane hit and burned part of the Pentagon, and the fourth crash-landed in western Pennsylvania. President George W. Bush responded by declaring a “War on Terror,” and the United States quickly invaded Afghanistan. With help from a few European governments, the Americans soon drove so-called Taliban fighters who sympathized with bin Laden from most of Afghanistan and installed an ineffective new government. Bush then attacked Iraq in 2002, where Saddam Hussein’s brutal, secular government precariously presided over an Arab majority, bitterly divided between Sunni and Shi’a forms of Islam (resembling Catholic–Protestant conflict of past times) and a discontented Kurdish-speaking Sunni population in the north. Easy initial victories in Iraq provoked years of sporadic violence, until 2008 when the Americans negotiated an agreement with an elected (but dubiously popular) government and promised to withdraw U.S. armed forces from Iraq within a few months. In the meantime, however, Taliban fighters had regained control of much of Afghanistan. Peace seems unlikely in any near future, especially since Muslim anger was heightened in late 2008 when Israel attacked Palestinians in Gaza with tanks and artillery.

Warfare—Japan and Korea

Military conflicts occasionally occurred between Japan and Korea in the first millennium CE, although scholars debate the nature or even the existence of permanent Japanese military outposts on the Korean peninsula. China was a participant or target of both nations, but Western involvement in war was not a factor for Japan and Korea until the late nineteenth and the twentieth centuries.

During the long histories of Japan and Korea, there were many times that their respective experiences with warfare would intertwine, with military forces moving from the Korean peninsula to the Japanese islands and vice versa on a number of occasions in the past two millennia. For the most part, however, warfare in Japan and Korea went their separate ways.

Premodern Korea

The great Chinese dynasties sought to control the Korean peninsula as one of many areas on the periphery of Chinese civilization. Thus, China's Qin and Han dynasties (221–206 BCE and 206 BCE–220 CE, respectively) both made attempts to conquer the peninsula. The Korean kingdom of Koguryo (37 BCE–668 CE) defended itself adroitly, but the Han did establish a commandery in present-day P'yongyang. As the Han declined in the early third century CE, however, two other kingdoms on the peninsula rose to increasing prominence—Paekche (18 BCE–663 CE) in the west and Shilla (57 BCE–935 CE) in the east, with Shilla—aided by China's Tang dynasty (618–907 CE)—eventually incorporating the other two in the seventh century to

form a single state. Kaya, a small tribal confederation in southern Korea had been subsumed into Shilla in the sixth century. The relationship between the various Korean kingdoms and the clans on the islands of Japan is hotly argued. Japanese textbooks maintain that there was a Japanese military outpost in southern Korea and that Japanese forces were called upon to aid the various kingdoms in their conflicts with one another in the fourth and fifth centuries, but many scholars, both Korean and Japanese, have insisted that there is no evidence of a permanent Japanese outpost and dispute the nature of Japanese military activity. Most scholars agree on the major contributions Korean culture made to what came to be the dominant culture in Japan in the early centuries CE.

One aspect of Shilla's social structure that contributed to its attaining preeminence over its neighbors was the *hwarang*, an elite group of young warriors who lived by a moral code that emphasized loyalty, filial piety, and courage; it also opposed indiscriminate killing. The Shilla kingdom also established a strong naval defense of the peninsula's coastal regions.

The Rise of Koryo

Shilla gradually lost control over its territories in the ninth century, and the kingdoms of Later Koguryo and Later Paekche asserted independence. In 918 a general of the Later Koguryo kingdom announced the establishment of the Koryo kingdom (918–1392), and in 935 Koryo defeated the remnants of the Shilla state. Koryo also defeated Later Paekche, and in 936 the Korean peninsula was reunited. The Koryo rulers constructed a wall along their northern border to help keep out marauding nomadic Turks and Mongols,

Sato Masakiyo Conquers Korea (1874). Triptych print in which elaborately uniformed warriors also rein in a horse and tame a tiger. Attributed to Utagawa Yoshikata. Signed by Ishinsai Yoshikata, engraved by Horiko Kanegoro.

and they alternately allied with the Chinese Song dynasty (960–1279) and the Khitan Mongols to help preserve their independence.

Koryo began to break apart in the twelfth century; invaded by the Mongols in 1231, it was a vassal state of the Mongol Empire from 1270. Like Shilla, Koryo was a strong naval power; its navy made use of cannon and gunpowder in the late fourteenth century and used naval guns to turn back a Japanese maritime invasion in 1380, destroying more than five hundred Japanese battleships.

The Choson (Yi) Dynasty

Weakened by its dealings with the Mongols, the Koryo kingdom fell in 1392 to Yi Song-gye (1335–1408), a military leader who had risen to prominence battling the Mongols. Yi became the first king of the Choson dynasty (1392–1910).

Perhaps the most famous element in Choson's military history is the development and deployment of the turtle ships—armored warships—in the sixteenth century. They were developed by the military hero Yi Sun-shin (1545–1598), who used them to repel the invasions of the Japanese general Toyotomi Hideyoshi (1536/7–1598) not once but twice, in the

1590s, though aid from China was decisive in defeating those Japanese forces that made it to land.

Premodern Japan

During Japan's Nara and Heian periods (710–794 CE and 794–1185, respectively), the aristocratic ruling elite made use of subordinate military clans for protection and to extend Japan's frontiers east and north, pushing back the indigenous population, the ancestors of today's Ainu (originally Siberian people now found only in Hokkaido, Japan's northernmost major island). These military clans became more and more powerful, until in the late twelfth century one clan, the Taira, became the de facto rulers of Japan, only to be replaced by a rival clan, the Minamoto, whose leader, Minamoto Yoritomo (1147–1199), ruled Japan as supreme military commander, or shogun. The Kamakura period that followed (1185–1333), named for the seat of Minamoto power, witnessed the beginnings of a distinctive Japanese feudalism. Samurai, as members of the warrior class came to be known, ideally lived ascetic, disciplined lives guided by codes of loyalty and honor. They could carry two swords—a long sword for fighting and a short sword for ritual suicide to atone for failings and embarrassments.

Japanese swords are famous for their hardness and sharpness.

The Mongol Invasion

After establishing the Yuan dynasty (1279–1368) in China, Mongol leaders looked across the narrow waters at Japan. The result was two great, Mongol-ordered, mostly Chinese- and Korean-supplied invasions of Japan, whose defeat gave rise to the kamikaze legend. In 1274 Khubilai Khan (1215–1294) sent forty thousand men on nine hundred ships to Hakata Bay, on the southern island of Kyushu. The Mongol-Korean army overwhelmed the Japanese defenders with the famed Mongol cavalry, explosive missiles, and powerful composite bows. As the Japanese retreated to the fortress of Dazaifu, and the Mongols to their ships in the harbor, a great typhoon blew through and destroyed more than two hundred Mongol ships, causing the invaders to retreat to Korea and China. In 1281 Khubilai Khan sent a larger army, 140,000 men, back to Hakata Bay. The Japanese had prepared by constructing a stone defensive wall, but the Mongol invaders enjoyed early success. But several weeks after landing, yet another typhoon, which Japanese religious leaders called a divine wind, or *kamikaze*, blew through and once again destroyed much of the Mongol navy and ended this threat to Japan.

Ashikaga Rule

The economic and military strain of defending Japan from the Mongol attack contributed to weakening the Kamakura government, which in 1333 was overthrown by an imperial claimant determined to return de facto power to the imperial throne. The claimant's initial backer, the general Ashikaga Takauji (1305–1358), eventually betrayed the cause and established himself as shogun, but Ashikaga rule (also known as the Muromachi period, 1333–1573) was much more decentralized than Kamakura rule had been, and Japan descended into civil war in 1467 that lasted for more than a hundred years. Toward the end of this century of war, Portuguese ships

arrived bringing missionaries and firearms, which, by making it possible for a peasant foot soldier to kill a mounted warrior easily, portended the eventual end of the samurai class.

Reunification of Japan

In the 1570s, three great unifiers ended the century of warfare. Oda Nobunaga (1534–1582) officially brought the Ashikaga shogunate to an end with his capture of the capital city of Kyoto in 1573; he was proceeding to bring Japan under his sway when he was killed by a vassal. Toyotomi Hideyoshi, Nobunaga's best general, completed the job of reunifying Japan. Although himself of humble origins, Hideyoshi reasserted the division between warriors and nonwarriors, confiscating swords and firearms from all nonwarriors in 1588. Dreaming of vaster empires, Hideyoshi attacked Korea with an eye toward China; upon his death the Japanese evacuated Korea. Hideyoshi, like Nobunaga before him, left only an infant heir, and like Nobunaga, Hideyoshi's eventual successor was an able general, Tokugawa Ieyasu (1542–1616), who established a new shogunal government with its capital at the city of Edo (present-day Tokyo).

The most salient feature of Tokugawa foreign policy was its closing off of Japan from the rest of the world. The Dutch—the only Europeans permitted to trade with Japan after 1639—were allowed only on the tiny island of Deshima in Nagasaki harbor; the Chinese were permitted entrance to Nagasaki itself. All other contact between Japan and the rest of the world was forbidden. Trade with Korea was permitted on the islands of Tsushima between the two countries. With the suppression of a revolt of Christian peasants and masterless samurai in Shimabara (in western Kyushu) in 1637–1638, Japan entered a period of peace that lasted more than two hundred years.

Nineteenth-Century Warfare

The coming of the modern West to eastern Asia in the mid-nineteenth century helped precipitate a

Utagawa Kokunimasa, *Our Army's Great Victory at P'yongyang Castle* (1894). Japanese officers look at maps and review the progress of battle taking place outside the fortress at P'yongyang. Library of Congress.

major change in Japan. The Tokugawa shogunate (1600/1603–1868) had grown old and had lost energy, and the arrival of eight ships under U.S. commodore Matthew Perry in the mid-1850s, demanding trade, helped bring it down. Samurai from provinces that had been on the periphery of power during the Tokugawa shogunate orchestrated the overthrow of the shogunate and called for the reestablishment of the emperor to power. After this Meiji Restoration (1868), Japan set about securing itself from European domination by modernizing itself furiously—not least its military.

War with China and Russia

In 1894, Japan intervened in internal Korean politics to force a Chinese reaction, which brought about the brief Sino-Japanese War (1894–1895). The small but modern and well-led Japanese army and navy quickly defeated the larger, older, outdated, and poorly led Chinese forces, which resulted in the Treaty of Shimonoseki, through which Japan gained Taiwan and the Liaodong peninsula of Manchuria. Its acquisition of the latter brought about the Triple Intervention of Russia, Germany, and France to preserve Russia's interest in China's northeast. Tension between Russia and Japan continued for a decade, culminating in the

Russo-Japanese War (1904–1905). A Japanese fleet attacked the Russian fleet at anchor at Port Arthur in southern Manchuria; fighting continued for more than a year. Hard fighting and huge losses sapped the strength of both sides, and they agreed reluctantly to a U.S.-brokered peace (the Treaty of Portsmouth). Japan had demonstrated its might not only against other Asian nations, but against a Western power. The Treaty of Portsmouth recognized Japan's interests in Korea, and, emulating Western imperialism, in 1910 Japan annexed Korea.

The Second Sino-Japanese War and the Pacific War

In 1931–1932, the Japanese seized control of Manchuria from China; in 1937 the second, and much larger, Sino-Japanese conflict began. Japanese atrocities during that conflict, including a massacre of 100,000–300,000 in Nanjing, have made for cool relations between the two nations ever since.

Japan's surprise attack on the U.S. Navy at Pearl Harbor in 1941 was designed to keep the United States from interfering in Japan's plans to build a self-sufficient empire in Southeast Asia. Following the attack, Japan took control of the Philippines, Indochina, Thailand, Burma, and the Dutch West Indies,

Hanosuke Kuroki, *Japanese and Russian Cavalry Troops Clash Near Chonju, North P'yongyang Province, Korea (1904)*. Library of Congress.

as well as numerous islands in the Pacific. When the tide started turning against the Japanese, privations at home grew great; the government encouraged the people by emphasizing the strength of the “Japanese soul”; recalling the thirteenth-century victory over the Mongols, young recruits were transformed into kamikaze suicide pilots to attack enemy ships. But in 1945, after experiencing two atomic bombs, Japan surrendered. The U.S.-imposed constitution required Japan to foreswear all future military aggression. Although the constitution forbade it, Japan now maintains a very credible Self Defense Force with an army, navy, and air force.

The Korean War

In August 1945, to fulfill a promise made at the Yalta Conference and reiterated at the postwar Potsdam Conference, the Soviet Union transferred a great many divisions to the Far East, sliced through the weakened Japanese army in Manchuria, and quickly moved into northern Korea. Meanwhile, beginning on 15 September, the U.S. Army's Fifty-Fourth Corps liberated Korea south of the 38th parallel. Within several years there were highly antagonistic regimes on both sides of the tense border and, on 25 June 1950, war erupted when 135,000 troops from the

north, backed by Soviet T-34 tanks, invaded the more lightly armed south.

The Korean War had five phases. The North Koreans pushed south, and U.S. president Harry Truman committed U.S. armed forces to slow the North Korean rush and to maintain a perimeter around Pusan, in the southeast, as a base for reinforcements and supplies. Beginning on 15 September, the United States, the Republic of Korea (South Korea), and some United Nations forces broke out of the Pusan Perimeter to link up with a daring amphibious invasion at Inchon. This counteroffensive carried the U.N. forces up to the Yalu River separating Korea from China and the Soviet Union. When the United States ignored Chinese demands to halt, the new Communist rulers in Beijing sent in troops, and in this third phase veteran Chinese Communist divisions slipped behind and around isolated U.S. and South Korean forces, driving them back across and slightly below the 38th parallel. Truman relieved General Douglas MacArthur of his command, and in the fourth phase the U.N. forces, commanded by General Matthew Ridgway, drove the Communists back across the parallel by early spring 1951. The fifth phase consisted of a twenty-seven-month period to negotiate the truce that currently reigns on the peninsula, where tensions continue to exist, fanned

in the twenty-first century by fears of North Korean nuclear weapons.

Warfare—Logistics

The components that support strategies and tactics of warfare—such as equipment, transportation, food, and housing—are called *logistics*. Modern developments that have improved military logistics include banks and lending institutions, railroads, and computers. In recent years people have used the term *logistics* to refer to an approach to supply-chain management in business and industry, particularly with regard to multinational corporations, that is based on military procedures.

The term *logistics*, first used by the Swiss military theorist Baron Antoine-Henri de Jomini (1779–1869) in his *Summary of the Art of War* (1837–1838), embraces troop mobilization, reinforcement, and replacement; weapons, ammunition, and matériel production, procurement, transportation, and handling; catering and canteen services; construction engineering; organization of military and civilian labor forces; equipment and maintenance; medical services; housing; pay and welfare; mail; fuel; and transportation of troops and supplies. To Jomini logistics was of equal importance with strategy and tactics, but his more influential contemporary, the Prussian military strategist Carl von Clausewitz (1780–1831), saw logistics as subordinate to them.

As soon as human groups began to fight one another, they discovered that their ability to prevail over an opponent required careful attention to providing their fighters not only with weapons but also with continuous access to all the necessities of life and doing so in such a way that their fighters could maximize their power, their mobility, and the range in which they could be effective. If the fighting force was

self-contained, carrying all of its necessary supplies, it would be powerful and move quickly but only for short distances. If the fighting force relied on local supply, feeding on the agricultural production of the area of operations, it could operate only in fertile areas during or just at the end of growing seasons. If it was supplied from bases that already existed in its own rear area or that were constructed as the force moved, it would be powerful and could range far but not quickly.

Ancient Warfare

Early in the second millennium BCE the Assyrian Empire deployed an army of more than a hundred thousand men. This army had a central military barracks with arsenals of weapons and a system for procuring the enormous number of horses needed for cavalry, chariots, and pack trains. Moreover, it had access to the services of a government bureau that provided forced labor for military building projects. Moving within the empire, Assyrian troops were issued travel rations from provincial supply centers, but after they moved beyond its borders and into enemy territory they lived off the land, which both diminished their need for a supply train and damaged their enemy's agricultural infrastructure. As much as possible, their line of advance took advantage of rivers and other waterways to transport materials, especially the huge siege engines, which were devices used to attack enemy fortresses.

People know of King Alexander of Macedon (Alexander the Great, reigned 336–323 BCE) for his brilliant leadership in battle, but his fabulous conquests were in large measure because of his careful and

Captain Eugene C. Cheatham of Montclair, NJ, serving with the Fifth Air Force's 67th Tactical Reconnaissance Wing at an advanced Korean airbase in July 1951, interprets aerial photographs taken by photo-reconn aircraft. National Archives.

thorough logistical arrangements. When he marched into Asia, he made sure that his troops carried as much gear and supplies as possible, eliminating the need for a long and slow train of baggage carts. He stayed close to the sea as long as he could and used inland waterways as well to utilize the superior carrying capacity of ships over carts. Often his spies and advance scouts bribed enemy officials not to destroy warehouses or crops before Alexander's troops could seize them, and he kept these officials on when he conquered their territory to take advantage of their ability and expertise. Ranging as far as India, he still managed to keep a line of communication back to Greece and Macedon to enable him to govern the full extent of his conquests and maintain a steady supply of reinforcements. With such arrangements his army could march 24 kilometers a day and covered 18,000 kilometers in eight years.

The ancient Romans were famous for building roads whose extent and engineering were a major element in the Romans' ability to move and supply their armies and create an empire extending from Britain to southwest Asia. Less noted was their development of the important logistical function of medical care, which was aimed not only at caring for those wounded in battle but also at ensuring the general health of the troops. Permanent Roman army camps had bathhouses to foster cleanliness, and the water from these bathhouses was used to flush the sewers

and latrines, which are a major health problem for any large military force. Every army camp, every large fortress, and even many smaller fortresses had a hospital staffed by doctors expert in amputation of limbs, extraction of arrows, treatment of skull fractures, and other necessities of military medicine. Armies on the move had field orderlies to assist the wounded on the battlefield and move them to field hospitals. These medical services played an important part in maximizing the power of the Roman army.

Medieval Warfare

Before the early modern era the biggest problem of logistics was the provision of an adequate and constant food supply for men and horses. The Mongol conquests of the twelfth century CE in south Asia, Central Asia, southwest Asia, and Russia, as well as the Mongol attacks into Europe, were made possible not only by their tactical audacity and innovations, but also by the fact that their horses could travel 96 kilometers a day and subsist on grass, unlike European horses, which needed large supplies of grain. The Mongol penetration of Europe was halted west of the central European plain largely by the unavailability of sufficient pastureland. The significance of horses in logistics is obvious from the Agincourt campaign of 1415 when the English king, Henry V (c. 1386–1422), had to scour his realm for the twenty-five thousand horses needed to mount the cavalry portion of the six thousand men he took to France and to haul supplies for the entire force. Henry's logistics train also included 60 grooms, 86 yeomen (attendants), 120 laborers, 120 miners, 124 carpenters, and 20 surgeons. To finance this effort, Henry had to take loans and break up one of his crowns to use the pieces as collateral.

Modern Warfare

We should not be surprised, then, that one of the greatest logistical breakthroughs in warfare was the development of banks and other financial institutions that let rulers and states raise more money for military

War is the unfolding of miscalculations. • **Barbara Tuchman (1919–1989)**

supplies and payrolls and to pay back the money over longer periods of time. This breakthrough enabled European states during the seventeenth and eighteenth centuries to keep professional standing armies and to equip them well. Even so, the expense of these armies and their supplies meant that the armies were kept relatively small and that they fought with a constant eye on their lines of communication back to their bases. When mass armies were recruited by Emperor Napoleon Bonaparte (1769–1821), they could stay in the field only by supplementing their stores with foraging. When Napoleon's Grand Army of 400,000 men invaded Russia in 1812, however, the army could not find enough forage. Its horses and men died in droves before they reached Moscow, from which they had to retreat over territory that they had already picked clean; only 30,000 men survived.

The Industrial Revolution transformed warfare by providing deadlier weapons and the means for manufacturing them in huge quantities and shipping them more quickly and less expensively. No invention of the time was more important than the railroad. During France's 1859 war against Austria, France deployed 604,000 men and 129,000 horses by railroad to northern Italy in just eighty-five days. During the U.S. Civil War, which began two years later, campaigns were built around the movement of troops and supplies by railroad, and railroads became targets of military action. The Prussian chief of staff, Helmuth Karl von Moltke (1800–1891), incorporated railway schedules into his plans for troop mobilization, deployment, and resupply, insisting that resources should no longer be wasted on frontier fortifications but instead should be used for the strategic development of railroads.

The organization of the complex process of industrial production was also important for the development of logistics. Using structures and concepts drawn from business firms, the Union Army during the U.S. Civil War developed the modern model of military medical services, integrating battlefield assistance to the wounded, evacuation to field hospitals, organized surgical care, and careful record keeping

to provide a seamless and documented treatment of the wounded.

The Two World Wars

The impact of industrial organization and production upon logistics became glaringly apparent in World War I. The very outbreak of the war was dictated by German planning that tied troop mobilization, deployment, supply, and operations so closely together that Germany could not respond to any mobilization of troops by any European power in any other way than by attacking deeply into France through Belgium, a war by timetable that failed in part because German planners put more troops on roads and railroads than could be moved rapidly enough to keep to the plan. Hostilities having begun, Germany had to supply its armies in France, deep inside Russia, and later in Romania while sending munitions and matériel to its allies Austria-Hungary, Bulgaria, and Turkey.

Britain had to move troops and supplies constantly across the English Channel, bring troops to Europe from India and Africa, and send troops from Britain to Turkey, the Balkans, Italy, and southwest Asia while battling German submarines in the approaches to the British Isles to assure a constant and sufficient flow of food and raw materials. All of the belligerents needed maximum production from farms and factories to keep their economies functioning while making war on an undreamed-of scale. The edge of the Allied powers (Russia, France, England, Italy, United States) was clear: between 1915 and 1918 they outproduced the Central Powers (Germany, Austria-Hungary, Ottoman Empire, Bulgaria) in coal production by 2.3 billion metric tons to 1.2 billion; in crude steel production by 150 million metric tons to 75 million; in aircraft frame production by 110,549 to 52,269; in aircraft engine production by 149,646 to 45,358; and in shipbuilding by 1,491 to 765. World War II featured even more impressive logistical feats, with the Allies (France, England, China, Russia, United States) producing seven times as many planes as the Axis (Germany, Italy, Japan), five times as many

trucks and artillery pieces, and four times as many machine guns and tanks. This material was delivered to the Russians by convoys around Norway, and to the Chinese by trucks via the 560-kilometer-long mountainous Burma Road or by plane from India over 24,000-kilometer-high mountains.

The Contemporary Era

During the years after World War II the superpower confrontation demanded the development of nuclear weapons stockpiles and increasingly sophisticated delivery systems alongside the maintenance of large armies and stocks of conventional weapons. At the same time peripheral wars such as those in Korea, Vietnam, Algeria, Afghanistan, and the Falkland Islands placed severe pressures on the military capabilities of the large powers and raised problems of rapid deployment and the use of special forces. During the post-Vietnam era the United States developed AirLand, a system of combined operations capable of meeting a Soviet offensive in Europe or deploying appropriate forces to Third World conflicts. Using this new mode of warfare in the 1991 Gulf War, the United States shipped 540,000 troops with 417,000 metric tons of ammunition; 300,000 desert camouflage uniforms; 200,000 spare tires; and 150 million rations into the theater of operations in less than four months. During the 2003 Gulf War, the 101st Division—17,000 soldiers; 5,000 vehicles; 1,500 shipping containers; and more than 200 helicopters—moved from Fort Campbell, Kentucky, to a forward base in Kuwait in just six weeks.

The handling of such complex tasks with such rapidity reflects the impact of the computer age on logistics, and just as the elaboration of operations management during World War II transformed business operations during the postwar era, so the military management of an almost infinitely complex supply chain has carried over into business. During

the past decade *logistics* has become a management buzzword, and business firms, whose procedures have often been adapted to military use, are adapting procedures tested by the military to conduct business on a global scale.

Warfare—Naval

The first recorded naval expedition took place about 4,500 years ago in Egypt. Although naval power has existed for millennia, it assumed indisputable importance with the wave of European exploration and colonization that began in the fifteenth century. Naval warfare has developed under three distinct phases—oars, sails, and steam—although new technologies such as batteries and nuclear power continue to develop.

Some form of naval power has existed since humans built their first cities along the great natural highways of the world: its rivers and seas. Navies developed to protect people, civilizations, and their waterways. When conflicts arose between nations, or when waterborne freebooters sought quick profit from those countries or their citizens, naval warfare often erupted.

Navies under Oars

The first record of a naval expedition is an Egyptian relief dating to 2450 BCE. Though each ship featured a large square sail, the vessel's single row of oarsmen propelled it into battle. An Egyptian temple carving of 1190 BCE depicts scenes from a large naval engagement against the Sea People. Archers provided ranged fire, stout bulwarks protected rowers, and spearmen in armor waited to fight their way aboard enemy vessels. The Ugarit Tablet, also dated to 1190 BCE, contains the first written report of a naval battle, fought between the Hittites and the Sea People off Cypress.

Despite the fact that navies arose throughout the Mediterranean, the topic of sea power is typically

associated with the rise of the Greek city-states because of the efforts of two early fifth century BCE historians, Herodotus, writing on the Persian Wars of the 490s and 480s BCE, and Thucydides, who wrote about the Peloponnesian War of 431–404 BCE. The navies described by Herodotus and Thucydides depended on galleys driven by one (unireme), two (bireme), or three (trireme) banks of oars. Also known as longships, these vessels featured high length-to-width ratios, relatively flat bottoms, bronze- or metal-sheathed wooden rams, and masts and sails for cruising. These galleys were extremely fragile and because of their shallow draught lacked holds to carry supplies. They typically operated within easy reach of land, both to shelter them from severe weather and to allow the crews to beach the vessels at night to forage, to water (the technical term for replenishing a ship's supply of water), and to prepare food. The roundship, of deeper draught, smaller length-to-width ration, and driven by sail and oars, served as the auxiliary vessel of the day. Their larger hulls transported troops and supplies. Roundships were often the critical element of any invasion (for example, the destruction by storm of a Persian support fleet in 492 BCE delayed an invasion of Greece by two years).

Though archery and boarding occurred during battles, the chief tactic of the time appears to have been ramming enemy vessels. Specific maneuvers emerged to support ramming, such as the *periplus* (the extension of the line of battle to flank enemy vessels), the *diekplus* (an attack in column to shear enemy oars and split the enemy battle line), and the *kyklos* (a circular defensive formation). Greeks also pioneered naval strategy, especially the interdiction of enemy supply lines through raiding or blockades

The battleship USS *Pennsylvania*, followed by a fleet of cruisers, supports an American landing in the Philippines in 1944.

and the naval support of invasions. Over time, other cultures placed their stamps upon the Age of Oars. For example, the Phoenicians developed superb navigational skills, while the Romans made ramming secondary to boarding, turning their superb legions into marines through the use of the *corvus* (a boarding ramp) and *harpax* (a machine to fire grapples).

Naval engagements under oars stretched across over four thousand years of recorded history, from the battles of Egyptians and Sea People to the last large fleet action between galleys at Lepanto in 1571 and beyond. Two events sounded the death knell of the oar-driven warship, the venturing of Europeans across the stormy Atlantic and the introduction of cannons. Together they would usher in a new era in naval warfare.

Navies under Sail

The powerful waves of the Atlantic called for a hardier construction than the gentler waters of the Mediterranean. The clinker-built longships of the Vikings served for raiding and eventual exploration and settlement of Iceland and Greenland, but it was the roundship that rapidly came to dominate European navies. Ideally suited for trade with their deep hulls, nations converted these merchant ships to warships in times

of conflict by adding a tower at the bow and stern. Soldiers supplemented the normal crew, ready to unleash arrows at the enemy before boarding; at Sluys in 1340, the English sent 250 ships against the French; all but three or four had formerly been merchantmen. Only with the development of the cannon would combat transition from an emphasis on melee to the use of the warship as a fire platform. The roundships stretched longer in relation to their beam, with cannons mounted along their sides to maximize firepower (thus firing “broadside”). Cannons, mounted on naval carriages that could be drawn inboard for rapid reloading, fired through closeable embrasures cut in the side of the vessel. The resulting shift in tactics was most noticeable during the confrontation between an English fleet relying on firepower and maneuver and a Spanish fleet more dependent on the older boarding techniques. This pivotal campaign of 1588 saw the Spanish Armada driven from the English Channel by a combination of English cannon and adverse weather.

Naval vessels also played the key role in opening the remainder of the world to European hegemony. Beginning in the late 1400s, Portugal’s naval vessels rounded Africa and began an exploitation of India and Asia that would be continued by, most notably, Great Britain. In the Western Hemisphere, Spain’s arrival in the New World signaled the beginning of

He is the best sailor who can steer within fewest points of the wind, and exact a motive power out of the greatest obstacles. • **Walter Scott (1771–1832)**

naval conflicts that lasted throughout the Age of Sail, as Spain struggled with England, France, and Holland for control of the new rich lands. As the Europeans squabbled among themselves, their American colonies rebelled, and in the process of rebellion found it necessary to rely on converted merchantmen, privateers (privately owned vessels sailing under a government commission known as a letter of marque), and allied naval forces to secure eventual victory.

The age of sail reached its apogee during the Napoleonic Wars of 1800–1815. Great Britain alone carried over a thousand vessels on its naval lists manned by more than 140,000 men and officers, and supported by the largest naval infrastructure in history. An estimated 20 percent of the adult population of England owed at least part of their livelihood to the British Admiralty by 1812, and the national treasury was rapidly depleted supporting that institution despite heavy tax rates and continued income from the largest merchant fleet in the world. The Battle of Trafalgar in 1805 confirmed the ascent of Britain's Royal Navy to world dominance. That dominance continued for another century, but the coal-fed fires of the Industrial Revolution soon eclipsed the Age of Sail.

Navies under Steam

Conservative naval hierarchies initially resisted use of the first steam engines, but by the mid-1800s, the advantages of an unwavering source of propulsion outweighed the disadvantages of dirty decks and space lost to coal bunkers. The Industrial Revolution created a pace of change in propulsion unheralded in earlier ages. In the 1830s steam engines driving side paddle wheels served as auxiliaries to sails. By the 1860s the navies of the American Civil War (1861–1865) developed ironclad hulls moved by steam-driven propellers. In the 1880s rapid improvement in steam engines allowed sails to drop to an auxiliary form of power. By the Spanish-American War of 1898 and the Russo-Japanese War of 1905, sails had disappeared from new warship classes. As World War I (1914–1918) approached, oil began to replace coal and the newest type of naval vessel, the

submarine, used electric batteries for subsurface propulsion. Less than fifty years later, nuclear powered warships began to move across, and beneath, the waves.

The Industrial Revolution also permitted changes in metallurgy, chemistry, and other sciences, which in turn accelerated change in all other aspects of naval technology. Whereas the ironclads of the American Civil War engaged at ranges of a few hundred yards or less, in 1905 the Japanese opened accurate fire on the Russians at over 5,000 yards. By the 1940s ships engaged at ranges triple those of 1905, and aircraft launched from carriers extended that range to hundreds of miles. By 2000 the use of ship- and air-launched missiles, as well as air-to-air refueling, moved the hypothetical engagement range well beyond 1,000 miles. Faced with ever deadlier weapons, strategies for ship protection were continually revised. At first designers fastened armor to wooden and iron hulls (ironclads). Later, steel hulls incorporated protective belts of armor across vital machinery and magazines, as well as thick turrets for guns. Increasingly after World War I, effective defense became more a matter of specialized weaponry in combination with lighter armor: sonar and depth charges against submarines, fighters to intercept enemy bombers, antimissile missiles and rapid-firing guns to destroy incoming warheads, and electronic countermeasures to baffle guidance systems.

The Next Wave

Navies will continue to exist and to change. Warships already feature automated guns, and satellites guide rockets with near perfect accuracy. But the next wave of technological developments cannot be accurately predicted. On the other hand, it is certain that when international conflict threatens, navies will feature prominently in its resolution.

Warfare— Post-Columbian Latin America

War is a constant theme in the history of Latin America. Soon after discovery of the New World in 1492, the Spanish and Portuguese fought and conquered the indigenous peoples. Between the fifteenth and twentieth centuries, wars for independence, indigenous uprisings, battles for rights to navigation and resources, and internal revolutions took place throughout the continent.

The collision of Eastern and Western Hemispheres that began in 1492 with the first voyage of Christopher Columbus unleashed a wide range of encounters on many planes, and war played a central role. The two largest wars of the age of sixteenth-century Iberian conquest in the Americas were won by Spain in Mexico (1519–1521) and in Peru (1532–1536). Historians generally attribute the final Spanish victory over the American empires to three major factors: (1) divisions among American peoples, some of whom opposed Mexican and Inca rule; (2) the effects of sudden, acute exposure to Eastern Hemisphere diseases, such as smallpox, to which Americans had no immunities; (3) the superior weapons and battlefield tactics of the Spaniards. The weapons advantages included steel-edged swords and pikes, crossbows, and cannons and infantry firearms. Armed with obsidian-tipped weapons, Mesoamerican warriors traditionally deployed in loose formations to capture victims for religious sacrifice, although Andeans, armed with clubs, deployed like Spaniards in massed infantry formations.

Portuguese colonization of Brazil began in 1500. The combination of disease, weapons technology, and tactics ensured the defeat of yet another group of indigenous Americans. Concerned about French

forays into Brazil, King João III of Portugal (reigned 1521–1557) redoubled colonization efforts in the 1520s. A final French incursion into present-day Rio de Janeiro was ejected by 1567. Latin America was divided between the overseas empires of Spain and Portugal.

Wars of the Colonial Powers

Spain and Portugal were concerned about preserving their American colonies and especially the bullion wealth that they produced, just as their rivals were interested in gaining access to them. Although it was not a major theater of operations during the Thirty Years War (1618–1648), England and Holland at times carried the war to the Western Hemisphere.

Armed ships of the Dutch East India Company forayed into the Pacific in 1614. That spurred improvements to fortifications of key Spanish harbors. Dutch and English activities in the Caribbean resulted in like efforts there. Dutch incursions into Brazil were eventually ejected, and in 1641 the Dutch capture of Luanda, Angola, was soon reversed, removing the threat to the transatlantic slave trade that had become the principal source of Brazilian plantation labor. The defensive posture assumed by the Iberian powers was for the most part successful, although a Dutch squadron once captured a Spanish treasure fleet off Cuba, and weakly defended Spanish Jamaica was lost to England.

The European powers fought a series of wars around the world throughout the eighteenth century, and the wealth of the Americas remained a central concern. Expanding British power heightened the threat to Spanish America. Technological and tactical

The Count d'Eu and Other Brazilian Officers who Took Part in the Paraguayan War (c. 1870). Photo by Albert Richard Dietze. National Library of Brazil.

developments in Europe were often mirrored in the Americas, but many American campaigns included guerrilla-style tactics as well as the fixed ranks characteristic of battle on the European peninsula. Small permanent American garrisons were often supplemented by militia units that also quelled internal rebellions.

British forces captured the Caribbean port city of Portobelo, in present-day Panama, immediately following the outbreak of the War of Jenkins's Ear between Britain and Spain in 1739. This conflict became enveloped in the War of the Austrian Succession (1740–1748). The heavy fortifications of Cartagena de Indias, in present-day Colombia, withstood a British siege in 1741. Another British squadron cruised the Pacific coast of Spanish America and then crossed to the Philippines. There it captured the annual Manila galleon, outbound from Acapulco and loaded with silver bullion.

During the Seven Years' War (1754–1763) Spain pushed Portugal out of Uruguay and went on to capture Rio Grande do Sul, the southernmost state in present-day Brazil. Britain captured Havana, Cuba, by taking the harbor fortifications from the landward sides. Also falling to British power was Manila, which prior to 1821 was administratively subordinate to Mexico City. Spain ceded Florida to Britain in exchange for Havana's return. Spain also received all

French territory west of the Mississippi River in North America, but at the price of the ejection of its French ally from the continent. Portugal later reestablished its town of Colônia in Uruguay but lost it again during the war that led to the independence of the United States (1776–1783). Spain provided monetary support to the rebels in North America and launched a successful campaign against the British that recovered Florida.

Rebellions and Independence Struggles

The Bourbon kings of Spain implemented political reforms that included heightened tax burdens on American subjects. Animosity increased between American-born white Spaniards and those born on the Iberian Peninsula. Consequently, Latin American colonies experienced many uprisings during the eighteenth century and later.

We can see many rebellions as responses to increased taxation and abuses by officials. Also important was cultural defense by anti-Spanish consciousness among indigenous villagers. Uprisings by African slaves occurred in areas where slave plantations were common. The larger rebellions often had multiple causes. Rebellions among Andean people often contained currents of Inca millenarianism, manifesting a desire to create an indigenous empire

One may know how to gain a victory, and know not how to use it. • **Pedro Calderon de la Barca (1600–1681)**

led by a descendant of the pre-1571 hereditary rulers known as Incas.

The most extensive of these rebellions took place in the Andes from 1781 to 1784. Some 15,000 regular and militia troops took the field against the Túpac Amaru II rebels, and an estimated 100,000 persons were killed during the rebellion. In the end royalist troops restored Spanish colonial authority. Rebels at times gained an initial advantage through surprise attacks, but they always suffered from a shortage of effective battlefield weapons. Although never the only factor, superior armaments enabled Spanish troops to defeat rebels in the end.

The prestige of the Iberian powers and the monarchs themselves provided a sort of final authority that held colonial rule together; Napoleón's invasion of Spain in 1808 upset this arrangement. Napoleon put his brother Joseph on the throne, wherefore guerrilla war broke out in Spain, while in the Americas, three separate independence movements arose. One was led by Simón Bolívar (1783–1830) and centered in present-day Colombia and Venezuela. José de San Martín (1778–1850) led another in Argentina and joined forces with Bolívar in Peru. The Mexican independence struggle erupted in 1810. Each conflict featured a large royalist faction that offered fierce resistance. Both sides had access to supplies of firearms and munitions, negating an important advantage enjoyed by royalists against earlier rebels. The conflicts were complex and protracted, but by 1824 all of Latin America except Cuba and Puerto Rico had achieved political independence.

Independence replaced two large colonial empires with a number of separate states. Each state faced many problems; prominent among them were disputes between liberals and conservatives that usually manifested themselves as conflicts over centralization of political power. Conflicts erupted within states over breakaway provinces and between states over borders and resources, some of which continue to the present.

The Portuguese king departed Rio de Janeiro in 1821 and left behind his son Pedro as prince regent. Pedro declared independence in 1822 and

implemented a centralist constitution. During the next twenty-five years five major armed rebellions occurred in different parts of Brazil, each one seeking to decentralize power. The Brazilian army defeated each in its turn. In 1835, the Brazilian government also suppressed a major slave uprising in Bahia.

Argentina failed to hold together the boundaries of the viceroyalty (the territory or jurisdiction of a ruler) of the Río de la Plata. The Bolívar faction in Peru created Bolivia out of Upper Peru. Paraguay, lying beyond effective reach of Buenos Aires, Argentina, achieved independence. Uruguay sought more local autonomy than Buenos Aires leaders wished to give, and the Spanish-Portuguese rivalry over that region reemerged as one between Argentina and Brazil. A lengthy conflict characterized by cavalry action followed. In 1828 Britain and France intervened to force the creation of a buffer state, not incidentally guaranteeing freedom of navigation on the Paraná and Uruguay rivers.

Wars against Indigenous Societies

Indigenous societies formed important parts of many Latin American states. Settled indigenous peoples had been largely incorporated into new nation-states in varying degrees of social subordination. Indigenous nomads resisted the onslaught of European-derived societies and attempted to maintain their ways of life. Argentina undertook its Campaign of the Desert (1833–1836) to eject the Pampas nations from lands intended for cattle ranching. Argentina achieved battlefield successes, but indigenous peoples continued to raid along the frontier of settlement. The Second Campaign of the Desert (1879) became largely aimed at Araucanian peoples who had migrated into Argentina because of Chilean military actions. Both Argentine campaigns ranged across large plains and were fought largely on horseback. During the second campaign especially, the Argentine army had superior weaponry and logistics and employed tactics similar to those used by the U.S. Army against Plains nations. Argentina's successful campaign resulted in the destruction of the indigenous nomads.

In a scene played out many times in modern Latin America, soldiers in El Salvador arrest students accused of revolting against the government.

Wars between Nation-States

Beset with internal conflicts between liberals and conservatives, Mexico also had to confront the westward-expanding United States. Mexico lost Texas to independence in 1836 and then faced U.S. pressure on California in the following decade. The United States declared war in 1846. After a land campaign in the north, the United States staged an amphibious landing at Veracruz and went on to capture Mexico City in September 1847. Mexico lost half of its territory. The U.S. victory can largely be attributed to the professionalism of its officer corps, effective use of mobile artillery, and state-of-the-art firearms. Internal conflicts between Mexican liberals and conservatives continued, leading to the War of the Reform (1857–1859). Liberal victory was followed by a conservative alliance with France, which in 1863 invaded Mexico and enthroned a puppet emperor. Liberals expelled the French in 1867.

In South America landlocked Paraguay disputed borders with all of its neighbors and sought expanded navigation rights to the Atlantic along the Paraná River. President Francisco Solano López (1827–1870) pressed his country's claims and embroiled it in a war against Argentina, Brazil, and Uruguay (1864–1870). Poorly equipped Paraguayan troops fought courageously but lost to the overwhelming force of its opponents; the male population of Paraguay was depleted by at least 50 percent.

Chile during the nineteenth century expanded to the north at the expense of Bolivia and Peru. At issue in the War of the Pacific (1879–1883) were mineral rights in

the nitrate-rich Atacama Desert. The Chilean army was outnumbered by its Bolivian and Peruvian opponents, but the Chileans were much better equipped and led by better-trained officers. Naval power was important in this war, although maintenance problems plagued the fleets of both sides. Victory gained for Chile the Atacama region and Peru's three southern provinces, of which northernmost Tacna was returned in 1929.

Loss of its Pacific coast turned Bolivia's attention toward the Paraná River route to the Atlantic. The unsettled Chaco region along the Paraguayan-Bolivian frontier contained oil and mineral reserves, and in 1932 Bolivia provoked a war with Paraguay over the Chaco region. Although Bolivia was expected to win because of its larger army and its aircraft, Bolivia's efforts to secure the region failed because soldiers from the highlands fell victim to disease when they entered the humid Paraguayan jungle and because Paraguayan generals deployed their forces effectively and kept them supplied by rail. Paraguay gained the lion's share of the spoils in the subsequent peace conference.

In the Caribbean, rebels started the third war for Cuban independence from Spain in 1895. Fierce guerrilla fighting continued for three years. Following an explosion that sank the U.S. battleship *Maine* in Havana, the United States declared war on Spain. Suffering defeats at sea and on land in Cuba, Puerto Rico, and the Philippines, Spain lost its last American and Asian colonies. The United States created a system of protectorates in the Caribbean and Central America that guarded the approaches to the Panama Canal (which opened in 1914).

Several Latin American states entered World War I, most notably Brazil, which was provoked by German attacks on its shipping. More countries declared war on the Axis powers (Germany, Italy, Japan) during World War II, including Mexico and Brazil, which allowed U.S. aircraft to use their airfields to combat the German submarine threat in the Atlantic. Brazil's army fought in Europe, and its navy escorted convoys across to Allied (United States, United Kingdom, France, Soviet Union, China) bases in Africa. A Mexican aircraft squadron fought in the Philippines during 1945.

In 1982 the military government of Argentina invaded the British Falkland Islands colony in the South Atlantic. Attempting to bolster public support for the military government, the junta (a group of persons controlling a government) sought to enforce Argentina's long-standing claim to the islands, which Argentina calls the "Malvinas." Despite the long sea lines of communication, a British expedition recaptured the islands. Argentine naval and air units achieved some success, but in general weaker Argentine forces faced British opponents who were trained to exacting North Atlantic Treaty Organization (NATO) standards. Britain's victory led to the fall of Argentina's military government.

Wars of Revolution

Between 1910 and 1920 Mexico experienced revolutionary upheaval and civil war. The Mexican Revolution began with the overthrow of Porfirio Díaz (1830–1915) and continued through a lengthy and complicated set of political twists and turns. Two short-lived successor regimes failed to consolidate power, and by 1914 a full-scale civil war raged across Mexico.

Three major factions emerged. South of Mexico City peasant followers of Emiliano Zapata (1879–1919) sought restoration of rural lands to their villages. Zapata's followers tended to fight on foot. The other two factions emerged in the north. Each drew heavily upon the cowboy population for its membership and made extensive use of horse cavalry. Throughout the revolution the railroad network constructed by the Díaz regime played a determining role in the ebb and flow of combat. The two northern factions also employed small aviation units. One northern faction was led by Francisco "Pancho" Villa (1873–1923), and the other by Álvaro Obregón (1880–1928), whose political loyalty lay with Venustiano Carranza (1859–1920). Villista and Carrancista forces both had access to U.S.-made weapons at first, but President Woodrow Wilson later cut off Villa's sources.

In April 1915 Villista and Carrancista forces clashed in two major battles around Celaya, northwest

of Mexico City. Villista cavalry mounted several charges against Carrancista machine-guns emplaced in barbed-wire defenses, resulting in decimation of Villa's forces. Retreating northward, Villa again faced Obregón at Aguascalientes on 10 July 1915, and suffered a crushing defeat that relegated the Villa faction to relative insignificance. A Carrancista column ejected Zapata's forces from Mexico City in the following month, and the Zapatistas retreated south into their home area of Morelos. Zapata himself fell victim to a trick and was assassinated in an ambush in 1919. The Zapatista forces lost cohesion and dissolved, ending the military aspects of the revolution. The Mexican Revolution was the largest-scale conflict in twentieth-century Latin America, but the revolution in Cuba affected many parts of the entire region.

In 1956 Cuban exiles led by Fidel Castro (b. 1926) landed in eastern Cuba and began a guerrilla war from mountain bases against the dictatorship of Fulgencio Batista (1901–1973). The Cuban military was outfitted with U.S. equipment from World War II and also jet aircraft. The difficult terrain afforded the rebels adequate security, and they quickly gained the support of peasants in the region. Thousands of troops moved against hundreds of rebels, but the guerrilla strategy succeeded. Castro's forces swelled to seven thousand as the public reacted unfavorably to repressive tactics employed by the Batista regime. (When Castro victoriously entered Havana, he had not clearly allied himself with the Communist Soviet Union.) A key factor in the rebels' victory was their high morale and good discipline. Operation from a remote base (*foco*) was a common strategy, and the Cuban Revolution served as a model for other revolutionary forces. However, only in Nicaragua did such a revolutionary force actually gain political power. Castro's Argentine-born comrade, Ernesto "Che" Guevara (1928–1967), died in Bolivia leading a failed *foco*-based revolutionary guerrilla force.

Warfare— Post-Columbian North America to 1775

Warfare in North America after the 1492 arrival of Columbus in the West Indies determined the settlement pattern of European colonization and rule, as well as the pattern of European–Native American relations, for the next four hundred years. It also established what some historians have termed the *American way of war*: a combination of the “surprise and ambush” tactics of Native American warfare and the heavy firepower of European warfare.

Post-Columbian warfare from 1492 to 1775 in North America (what is today Canada, the United States, and the islands of the Caribbean) can be divided into three major types. The first type is the conflicts that were primarily between various Native American groups, the second is the campaigns of conquest conducted by Europeans against a variety of Native American tribal groupings, sometimes with other Native Americans allied to the Europeans. The third and most significant campaigns are those of Europeans against other Europeans with some supporting Native American allies on one or both sides. This article will focus on the second and third types and touch only briefly on the first, since much of that type of warfare is poorly documented at best.

Characteristics of Native Warfare

It is a commonly held misconception that the Native American style of warfare was more ceremonial or more of a dominance ritual than warfare as fought by the Europeans. Just as the Europeans waged war for territory and power, Native Americans primarily waged campaigns to expand or defend hunting-and-

gathering areas or regions of cultivation and to secure captives either to replace losses or to serve as slaves.

These native wars were characterized in North America by techniques suitable to a hunting-and-gathering culture, relying more on ambush and surprise attacks than on set-piece battles. Within those constraints, however, combat was ruthless and brutal with little concern for “noncombatant” casualties. Especially in surprise attacks on an enemy’s villages, women and children were not spared unless to be taken as captives. While war was seldom waged to intentionally annihilate an enemy tribe, often times the casualties would be significant enough to cause one side or the other to have to assimilate with neighboring groups, thus effectively ceasing to exist as a separate tribe.

One major exception to these general conditions is the creation of the Iroquois Confederation in the later years of the 1500s and the early 1600s, in what would become upstate New York. The Iroquois, while maintaining many of the characteristics of native warfare, were also in the midst of what can be called an “imperial” expansion of their own, conquering territory and subjugating neighboring tribal groups.

Characteristics of European Warfare

The Europeans in a sense had a much more stylized form of warfare with set-piece battles fought almost by arrangement and extended sieges of cities and fortresses. Like the Native Americans, Europeans fought primarily to expand or defend border provinces and to acquire coercive power over their neighbors. In the sixteenth and seventeenth centuries, this coercive power was often related to the religious beliefs of

Wilhelm Lamprecht, *Father Marquette and the Indians*. In 1673 the French Jesuit missionary, along with Louis Jolliet, mapped the northern portion of the Mississippi River. Haggerty Museum of Art at Marquette University, Milwaukee, WI.

the states or groups involved as the struggle between the emerging Protestant sects and the formerly hegemonic power of the Catholic Church intensified.

Battle was a difficult event to orchestrate with the armies taking hours to draw up in their combat formations, thus battle was sometimes engaged by mutual consent of the opposing commanders. Battle was waged by generally linear formations of infantry equipped with firearms and pike, with massed cavalry and relatively static artillery in support. Due to the disciplined and well-armed forces, casualties on one or both sides could equal or exceed 50 percent of the engaged armies. Due to the nature of seventeenth- and eighteenth-century maneuver and battle, the more prominent form of combat was the siege of a fortified city or independent fortress. These sieges had become very formalized with an almost mathematical precision to their course and outcome.

The “American Way of War”

In North America, these two conflicting styles would combine, resulting in a synthesized form of warfare that was characterized by both the surprise and ambush of Native American warfare and the heavy

firepower of European warfare. In addition, as the settlers saw their very survival at stake on the frontier, these conflicts took on the character of a total war of annihilation as opposed to the more limited goals of either Native American warfare or European state warfare. This intensity of conflict often surprised and shocked both Native American enemies and European observers. It is from these origins that the American tradition of total war and unconditional surrender arose.

The Impact of Disease

In addition to the increased intensity of warfare in North America, disease played a dramatic role in many of the conflicts as the Eurasian disease pool was introduced into North America among people who had no developed immunities. The impact of smallpox, measles, and other endemic diseases of Europe were devastating on the Native American populations, often resulting in near total collapse of the native tribes and the decimation of their populations. Likewise, however, certain diseases endemic in the Americas or tropical diseases, such as yellow fever and malaria, could lay low entire settlements or armies of Europeans.

The Impact of Technology

The technology of the Europeans had a profound impact on the Native Americans, both on the battlefield and within their varied cultures. The combination of horse, rider, armor, firearms, and steel weapons was formidable, especially in the early years of Spanish settlements and conquest. The only counter the Native Americans had was either to overwhelm their European opponents with numbers or to strike quickly from ambush and escape before the Europeans could effectively respond. The other problem that European technology created was a dependence on trade with the Europeans on the part of the hitherto self-sufficient Native American warriors. The guns that the Europeans introduced required powder and shot as well as either replacement or repair in the event of failure; the Native Americans were not sufficiently equipped culturally or technologically to produce their own or even to repair broken weapons in most cases.

Intertribal Warfare in North America

Although the European arrival, settlement, and advance caused the most intensive conflict in the post-Columbian New World, it would be a mistake to assume that conflict between Native Americans tribes died out. Instead, in some ways the presence and effect of the Europeans intensified this intertribal warfare.

One major source of conflict among the Native Americans was the rise of the Iroquois Confederacy, the dominant native power and a nascent empire on the rise in the northeastern part of what would become the United States. The case of the Iroquois is unusual in that initially five tribes, later six, banded together in pursuit of common goals in a power-sharing arrangement. The member tribes of the Iroquois Confederation agreed not to wage war on one another and combined their power to subdue their neighbors and to dominate trade in the region. The power of the Iroquois Confederation was felt north into New France and south as far as the Cherokee lands in the Carolinas, Tennessee, and Georgia. Though the

Iroquois rise predates European settlement in North America, the confederation continued to expand its area of influence, often playing one colonial power off against another to maintain its position.

Tribal warfare also continued along the edges of colonial areas as the various tribes fought over trading rights with the newcomers. European trade goods had a tremendous draw for the Native Americans, everything from firearms and steel axe heads to cloth and iron cooking pots, to say nothing of European or American distilled liquor. These trade goods fundamentally altered the traditional relationships between tribes. In order to gain control of the highly desired trade goods, the tribes needed access to both the Europeans and to the furs and other native products the Europeans desired in return. Thus wars broke out between tribes for control of this trade in addition to the ancient fights over hunting and agricultural territory and for slaves and honor.

Among the Europeans, the French were perhaps the most influential of the newcomers with their fur-trade-driven economy. The French courted the tribes with trade goods and alliances. As a result French influence spread far into the heart of the American continent with both the *voyager de bois* and French Jesuit missionaries active as far west as the trans-Mississippi region. They participated with their allies in intertribal warfare, often having a decisive impact despite their small numbers because of the technological advantages they possessed and brought to their allies.

The European arrival also set in motion intertribal warfare far from their actual zones of conflict as the effects of European arrival set in motion two powerful factors. As Eurasian diseases made their way across the continent, epidemics devastated some tribes, upsetting local balances of power, generating wars as the lesser-affected tribes expanded their territories into territories of the more severely affected tribes. The European arrival also set tribes in motion as they were displaced from east to west; this displacement also caused wars between tribes as the refugees pushed west. One result of these displacements was the arrival of such tribal groupings as the Lakota on

the Great Plains in the 1700s, having been pushed out of the woods of Wisconsin and eastern Minnesota by the Ojibwa (the Chippewa). The Lakota then pushed the Crow tribe off its territory, and the ripples moved west.

Horses, initially brought to the Americas by Spaniards, changed life and warfare on the high plains when runaways began to thrive on the prairie grasslands after about 1600. Indians were already familiar with bows and learned quickly how to shoot their arrows from the back of galloping horses. Suddenly, buffalo hunting became a way of life, agriculture diminished, and warfare became mobile as never before, turning into cavalry encounters between rival tribes seeking to secure their hunting grounds. Warlike Plains Indians met Spanish and American soldiers, even when armed with guns, on more nearly even terms than before, winning their last battle in 1876 against General Custer of the United States Cavalry.

Europeans against the Native Americans

With the beginnings of colonial activity and expansion of European powers into North America, each European country extended its power in service of its own interests. Thus the indigenous people faced encounters ranging from violent conquest and displacement to alliance and trade.

The Spaniards

The European campaigns against Native American tribes began with the earliest landings in the Caribbean by the Spanish. Small groups of Europeans were incredibly successful in the face of generally overwhelming numbers. The Spanish set the example for this both with their relatively easy conquest of the Caribbean Islands of Hispaniola and Cuba, as well the smaller islands and their later conquests in Mexico and Peru. The keys to their success were the differing approach to warfare between the Europeans and the Native Americans, the superior technology of

the Europeans, intertribal differences, and the impact of disease.

The initial Spanish forays into the North American continent were exploratory expeditions, which operated more as raids, searching for more wealth, as had been found in Mexico and Peru, and when not finding it, moving on. Oftentimes, their meandering was more the result of rumors spread by native leaders than deliberate routes planned by the explorers and conquistadors. The Spanish generated hostility by their incessant demands for food and gold that resulted in the local natives offering various levels of noncooperation or resistance. These early expeditions, especially the efforts of Hernando de Soto, beginning in Florida and wandering as far north perhaps as the Carolinas and then west to the Mississippi Valley, were unsuccessful in locating any vast new areas of riches. However, both de Soto's expedition and Coronado's through the American Southwest as far north as Kansas did provide valuable information on the native peoples and basic weather and terrain conditions.

Subsequent Spanish expeditions established settlements in Florida and Southwest, especially in New Mexico. These settlements were a combination of military outposts and missionary churches. The Spanish were generally able to overawe the natives with firearms, steel, and cavalry, to which the native tribes of the Southeast and Southwest had no effective answer. The Spaniards were very careful to prevent firearms and, initially, horses from falling into the hands of the Native Americans.

The relatively easy, though at times violent and bloody, conquest of the borderlands was tested in 1680 by a widespread uprising of the Pueblo Indians. Drought and high temperatures as well as increasing Spanish demands on the Pueblos, combined with a series of successful raids by Apaches, Navajos, and Plains Indians, resulted in the first unified uprising against the Spanish in New Mexico. It would be thirteen years before another expedition would reconquer the province of New Mexico. By 1700 the Spanish had again occupied the Pueblo territory and reestablished

settlements, decimating the Pueblo population in the process. After 1700 the Spanish continued to expand the area under their direct control, and while they met continued opposition from native groups, the basic pattern remained the same, small numbers of Spaniards overawing larger numbers of natives. However, when the natives were incited and supplied, as well as supported, by other Europeans, the conflict took on the characteristics of an imperial border war.

The French

The French in New France and the Mississippi River Basin had a much different experience in that the French were not interested in large-scale settlement and agriculture or mining. Instead, they were interested in the fur trade, which required the cooperation of the Native Americans. Therefore, with few exceptions the French chose to establish very good relations with the natives and in fact offered their active support against their friends' traditional enemies, such as the Iroquois. Thus, very quickly the warfare on the French frontiers adopted the characteristics of imperial border warfare, with both Europeans and Native Americans on both sides of the conflict.

The Dutch

The Dutch established settlements in what is today New York prior to the settlement of the English Pilgrims and Puritans in New England. The Dutch, while interested in settlement and agriculture, were also very interested in the fur trade, which resulted in a bifurcated policy, on one hand displacing Native Americans in the Hudson River Valley, and on the other operating as suppliers and sometime allies to the Iroquois of the northern and western frontier areas. Dutch penetration into the Connecticut River Valley in the 1630s helped to bring on the Pequot War, which was primarily but not exclusively fought by English settlers against the Pequot tribe.

The English (British after 1701)

The British were almost exclusively interested in acquiring land for agricultural use, which entailed the displacement of the local native tribes and much resultant warfare. The English settlers brought from England the tradition of the militia; all military-age males were required to provide their own weapons and train a specific number of days a year and were liable for service within the colony. The English settlements relied on this militia force for both its defensive capability and its offensive capability against Native Americans and other threats to the security of the colony.

The most significant problem the English settlements faced was their dispersal on farms and in small villages along the frontier. As the frontier advanced inland, the Native Americans had a ready and vulnerable set of targets to strike at with their traditional raid and ambush tactics. The English responded by fortifying houses in the villages, launching periodic punitive campaigns against the Native Americans, and conducting active militia patrols and ambushes along likely Indian approaches during times of trouble. The English faced repeated uprisings and minor wars with native tribes from 1622 in Virginia until 1675, in both King Philip's War in New England and Bacon's Rebellion in Virginia, as well as many other conflicts along their expanding frontiers.

Imperial Warfare in North America

Various forms of conflict between European powers in North America and the waters along its coasts and in the Caribbean began in the middle portion of the 1500s as the Dutch rebelled against Habsburg Spanish rule. Their naval and privateer forces, later joined by English privateers, attacked Spanish settlements and treasure ships. About a century later, the Anglo-Dutch Wars of the 1650s and early 1660s also slipped over into North America, with the English gaining control of the Dutch settlements along the Hudson River from Albany in the north to New Amsterdam in the south. The English renamed the colony

and the major port city at the mouth of the Hudson: New York.

It was, however, between the French and the English that the longest, most costly, and in the end most significant of these imperial wars was waged. Between 1689 and 1763, the English and the French faced off in a series of four separate yet interrelated conflicts. These conflicts were characterized by a blending of frontier-type warfare, reminiscent of native warfare with numerous bloody but brief ambushes and raids along the frontier, and the more traditional European-style confrontation of siege and set-piece battle, though the numbers involved in these battles were generally very small compared with their European counterparts.

These wars grew in scope and intensity throughout the period. By 1763 the British had committed a significant portion of their regular army to the colonial struggle in North America, but not before they generated increasing colonial resentment for what were perceived as disappointments, broken promises, and outright betrayals of the colonial cause. Early on, the British colonists had determined that their security would never be insured and their ability to expand into the interior would be constrained until the French had been driven from both Canada and the Ohio and Mississippi river basins. For the colonists this was not a case of a series of imperial border wars between the mother countries, their colonists, and their native allies. It was instead a war of survival, and in order to survive, the French and Indian threat had to be destroyed at its source: the French settlements along the St. Lawrence and the fur trading posts along the lakes and rivers of the interior. It was not until 1758 that the British government under William Pitt the Elder adopted the same view.

It was during the fourth and final war, the Seven Years' War in Europe or the French and Indian War in North America, that all the components of warfare in North America came together: extended large-scale border ambushes and raids conducted by Native Americans allied with local militia or European regulars, the largest of these being Braddock's

defeat on the Monongahela River in 1755; large-scale European-style sieges of Fort William Henry, Louisburg, and Quebec (though Louisburg had been besieged several times before); and, finally, the single largest European-style set-piece battle fought out on the Plains of Abraham near Quebec, which signaled the end of French rule in North America (though the peace treaty would not be signed for another four years).

The final significant aspect of post-Columbian warfare in North America occurred shortly after the Treaty of Paris in 1763 when unrest among former French-aligned Native American tribes broke out in what is commonly and mistakenly referred to as Pontiac's Rebellion. In an attempt to pacify the Indians, reduce costs, and minimize frontier warfare, the British adopted what is known as the Proclamation of 1763, which attempted to limit colonial expansion. It failed to limit expansion and only further inflamed colonial resentment already high over British hesitancy in the long period of warfare, newly reimposed mercantilist policies, and newly enacted taxes on the colonies to pay for the cost of the wars. In the end all this combined to produce the American Revolution in 1775.

Warfare— Pre-Columbian Mesoamerica and North America

The earliest evidence of specialized arms for warfare in Mesoamerica dates to post-1150 BCE in Mexico. While North American weapons were used primarily for hunting (at least before 900 CE), Mesoamerican weaponry emphasized hand-to-hand combat and was designed to capture and kill people. Despite this greater emphasis on weapons, perhaps the most crucial element of Mesoamerican warfare was organization and discipline.

The identifiable history of specialized weaponry in pre-Columbian North and Middle America begins some three thousand years ago against a backdrop of knives, spears, and atlatls (spear throwers). These implements probably formed part of the tool inventory that accompanied the first migrants into the New World. Although they could be turned to martial use, they were primarily used for hunting animals. Armed conflicts at this point probably involved clashes between rival groups, with the weaker fleeing from the without engaging in sustained confrontations.

Emergence of Warfare

Warfare became more important after the development of the settled, agricultural communities that became widespread in Mexico between 2500 and 1400 BCE, but much later further north. (Although this article covers both North America and Mesoamerica, it will concentrate on Mesoamerica, as the development of complex society, including warfare, was more developed much earlier there, and the archaeological record is richer.) The creation

of settlements paralleled the growth of political complexity and specialized weapons, which do not emerge in isolation but require complex social support. The earliest evidence of such weaponry occurs with the Olmecs of the southern Mexican Gulf coast after 1150 BCE.

Hunting tools such as atlatls were used, but it was clubs, maces, and stone-tipped spears that emerged as the most important weapons. Clubs, maces, and spears used as staff weapons (a blade set on a staff, such as a halberd in Europe) are quintessentially martial arms. Designed to capture and kill people, these arms required specialized training.

These weapons also emphasized hand-to-hand combat; spears were used for thrusting and slashing rather than throwing, and clubs and maces were used as crushers. Hand-to-hand shock weapons, not projectiles, dominated early Olmec battlefields. Defensive arms—shields, helmets, and armor—were rare among the Olmecs, perhaps reflecting their monopoly of specialized weapons of war. Whether the Olmecs employed their forces individually or in organized formations is unknown, but given the low populations of Olmec settlements—with maximum populations of about 1,500 to 2,500 people per settlement—Olmec armies were almost certainly small. Some soldiers may have accompanied merchants traveling throughout Mesoamerica, though they were for the most part employed domestically, a fact that is more easily understood when one realizes that typical march rates without roads averaged approximately 19 kilometers per day. Even merchants used dirt trails because formal stone roads had yet to be developed. The appearance of slings and spherical stone and clay shot by 900 BCE gave the Olmecs an

Folio 65 (recto) from the Aztec *Codex Mendoza*, created circa 1541. The attire worn by warriors corresponds to their military achievement; the top half depicts men intending to become priests, the bottom shows imperial officers.

effective projectile capability, which, combined with their shock tactics, let them dominate the battlefield for the next half millennium. And their way of war spread with them.

The Olmecs had stretched over much of central Mexico and down the Pacific coast as far as El Salvador, but around 550–500 BCE, they began withdrawing from these outlying settlements and apparently retreated back into their heartland on the Gulf coast of southern Veracruz / northern Tabasco. Following the Olmec withdrawal after 500 BCE, thrusting spears dominated elite warfare in Mesoamerica. Clubs persisted among nonurban groups, but along with maces they became less common as the use of

helmets and large wood, cane, and leather shields spread. Faced with these defenses, warriors turned from clubs and maces to longer, lighter cutting, and penetrating arms. Armor also reduced the effectiveness of slings. The appearance of large bodies of opposing soldiers also suggests the emergence of formations. Specialized fortifications also emerged: there were fortifications at smaller sites for protection, but larger ones arose to dominate local regions. Walls at least tripled the strength of defenders, minimized logistical problems, and permitted the use of a larger percentage of the populace. Walls give defenders a major advantage over attackers by giving them places from which to fight with maximum protection—and with food and other supplies close at hand—while forcing the attackers to expose themselves with little or no protection. Some walls were accompanied by extensive dry moats, but many were hilltop fortifications whose altitude multiplied the difficulty of assaults.

Organizational Innovation at Teotihuacán

The next major development was organizational, combining units with reinforcing arms. At Teotihuacán, the great city of central Mexico that flourished from approximately 150 CE to between 650 and 750, some soldiers used thrusting spears and bucklers that increased mobility, while others wielded atlatls and darts with rectangular shields that offered less mobility but greater protection. These shock and projectile weapons units reinforced each other, firing on the enemy from a distance (the effective range of an atlatl was approximately 53 to 63 meters), while the spearmen closed in for hand-to-hand combat. Superior helmets of cotton quilted between fabric also appeared, affording enough protection to permit the use of smaller shields.

Using complementary units halved the number of combatants who could be brought to bear at any one time, but Teotihuacán extended military training beyond the elite, allowing it to field far larger armies than was possible when warfare was the domain of

Folio 67 recto of the *Codex Mendoza*: (top) warriors scout a town at night in preparation for an attack; (middle) negotiations after surrender; (bottom) high-ranking commanders.

the elite only. Teotihuacán's more open system was not adopted in other cities in Mesoamerica, but its arms were, which perhaps accounted for Teotihuacan subsequently adopting armor. By 500 CE, two types of quilted cotton armor some five-to-eight centimeters thick were in wide use in Teotihuacán's armies. One was a full-body armor that covered all the limbs; the other was a quilted tunic reaching the knees. Both types were proof against atlatl darts fired from a distance, most spear thrusts, and virtually all stones fired from a sling.

Armor, however, was extremely costly, as all the cotton had to be imported and extensively worked, so it was probably worn by only a minority. A greater problem was that it restricted the wearers' mobility.

The advantages armor did offer were not enough to stop the tide from turning against Teotihuacán, which fell by 650–750 CE.

During Teotihuacán's heyday, permanent settlements had also emerged in North America, and by 600, bows and arrows had spread throughout North America. At this time, there were no bows and arrows in Mesoamerica; they arrived around 1100 or shortly thereafter. Their use spread southward from the north, presumably having come originally from Asia. Bows were mainly hunting tools, but they could be used as weapons that could strike effectively at a distance and from ambush. So while there is little evidence of sustained combat in North America, clashes became more deadly.

With Teotihuacán's demise, sizable organized armies largely vanished. Among the Maya, where armor was rare, clubs and maces persisted, often coupled with bucklers, while spearmen used long, easily transportable flexible shields. Stone-pointed thrusting spears continued to dominate, but some now boasted serrated blades running down both side of the shafts as far as a foot to produce longer slashing surfaces while remaining light.

Maya innovations spread into central Mexico around 700 CE. Thrusting spears were adopted, along with round shields carried on the left wrist to free that hand, but armor was gone. Combat was lighter and more mobile, but unsuited to large-scale conquest, and was associated with groups in hilltop fortifications rather than with conventional armies.

Developments in North America

Warfare was becoming endemic in North America after 900 CE, owing at least in part to the increased reliance on a better array of crops (notably corn), which led to larger, more tightly-knit and clustered settlements and the political leadership that comes with them. Armed with bows and arrows, nomadic groups preyed on the settled, and settled groups also clashed with each other. As time went by,

warfare became more organized and complex, especially in the Southwest and Southeast after 1000 CE. Many settlements became centralized, defensive sites were occupied, and military societies emerged, though with the exception of what may have been oak swords, little new weaponry was developed. In the Southeast, no armor emerged, but bladed clubs were used, indicating specialized warrior groups, and major towns now had palisades, all signs of more centralized polities. Heads were taken as trophies.

Developments in Mesoamerica, 900–1200

The next major shift in central Mexico came with the Toltecs, the major power in the region from approximately 900 to 1200. The Toltecs combined atlatls, knives, and a curved, bladed, wooden short sword with round shields and light body armor. The wrist-borne shields freed the left hand to carry darts, which soldiers could fire until they met the enemy, whereupon they shifted to swords: a single combatant thus had both projectile power prior to closing and a light shock weapon. Fortification declined with the rise of this offensive emphasis.

Arms and armors did not change significantly in the Maya area at that time, except as they were introduced from central Mexico. But one development had a significant military consequence. In some areas, Maya roads built for all-weather, swift movements were used to link internal political regions militarily.

Siege craft was never well developed in Mesoamerica, owing to logistical constraints that rendered it extremely difficult to maintain an attack on a distant region unless walls could not be quickly breeched or scaled with ladders. There is evidence of a stationary siege tower built to pour counterfire on the defenders of a pyramid temple in tenth-century Yucatán, but generally combat comprised the clash of opposing armies, and Toltec light infantry

dominated the battlefield until their downfall. The Toltec demise may have been hastened by the influx of peoples from the ever-drier north, who brought bows and arrows into central Mexico for the first time and disrupted the flow of trade with their hit-and-run tactics, against which large conventional armies were ill suited.

Aztec Warfare

The Aztecs, who became established in central Mexico in the early 1300s and whose empire flourished from 1430 to 1521, made the last major weapons innovations. Under their empire, a preindustrial military complex supplied the imperial center with materials not available locally, or manufactured elsewhere. The main Aztec projectiles were arrows shot from bows and darts shot from atlatls, augmented by slingers. Arrows could reach well over a hundred meters—and sling stones much farther—but the effective range of atlatl darts (as mentioned earlier, about 60 meters) limited the beginning of all barrages to that range. The principle shock weapons were long, straight oak broadswords with obsidian blades glued into grooves on both sides, and thrusting spears with bladed extended heads. These arms culminated a long developmental history in which faster, lighter arms with increasingly greater cutting surface were substituted for slower, heavier crushing weapons. Knives persisted, but were used principally for the coup de grâce. Armor consisted of quilted cotton jerkins, covering only the trunk of the body, leaving limbs unencumbered and the head free, which could be covered by a full suit of feathers or leather according to accomplishment. Warriors also carried 60-centimeter round shields on the left wrist. Where cotton was scarce, maguey (fiber from agave plants) was also fabricated into armor, but the long, straight fiber lacked the resilience and warmth of cotton. In west Mexico, where clubs and maces persisted, warriors protected themselves with barrel armor—a cylindrical body encasement presumably made of leather.

City walls and hilltop strongholds continued into Aztec times, but construction limitations rendered it too costly to enclose large areas. Built in a lake, the Aztec capital of Tenochtitlán lacked the need for extensive defenses, though the causeways that linked it to the shore had both fortifications and removable wooden bridges.

By Aztec times, if not far earlier, chili fires were used to smoke out fortified defenders, provided the wind cooperated. Poisons were known, but not used in battle, so blowguns were relegated to birding and sport. Where there were sizable bodies of water, battles were fought from rafts and canoes. More importantly, especially in the Valley of Mexico, canoe transports were crucial for deploying soldiers quickly and efficiently throughout the lake system. By the time of the Spanish conquest, some canoes were armored with wooden defensive works that were impermeable to projectiles.

The Importance of Organization

Despite the great emphasis placed on weaponry, perhaps the most crucial element in warfare in Mesoamerica was organization. Marshaling, dispatching, and supplying an army of considerable size for any distance or duration required great planning and coordination. Human porters bearing supplies accompanied armies in the vanguard (the body of the army); tribute empires were organized to maintain roads and provide foodstuffs to armies en route, allowing imperial forces to travel farther and faster than their opponents; and cartographers mapped out routes, nightly stops, obstacles, and water sources to permit the march and coordinate the timely meeting of multiple armies at the target.

What distinguished Mexican imperial combat from combat in North America was less technological than organizational. More effective weapons are less important than disciplining an army to sustain an assault in the face of opposition; that task requires a political structure capable not merely of

training soldiers, but of punishing them if they fail to carry out commands. Politics with the power to execute soldiers for disobedience emerged in Mexico but not in North America; those politics had a decisive advantage over their competitors.

In North America, chiefdoms dominated the Southeast beginning after 900 CE, and wars were waged for status and political domination, but the chiefdoms of the Southwest had disintegrated after 1200 CE, and pueblos had emerged from the wreckage. (We use the term *pueblos* to refer to the settled tribal communities of the Southwest, but chiefdom is a political term that reflects the power of the chief, which was greater than that exercised by the puebloan societies after the collapse around 1200 CE.) There too warfare played a role, though for the pueblos wars were often defensive engagements against increasing numbers of nomadic groups. The golden age of North American Indian warfare emerged only after the arrival of Europeans, their arms, and horses. But even then, in the absence of Mesoamerican-style centralized political authority, individual goals, surprise attacks, and hit-and-run tactics dominated the battlefield, not sustained combat in the face of determined opposition.

Warfare— Pre-Columbian South America

Indigenous South Americans apparently waged war for many of the same reasons as other peoples: to control land, natural resources, human labor, and trade. Most of what we know about Andean warfare in South America comes from carvings and pottery, and it indicates an emphasis on violence. Less clear is whether the apparent predatory and cannibalistic behaviors in Amazonia were aggravated by European colonialism.

South America was a relatively isolated continent before 1492. It thus provides us with interesting opportunities to compare world-historical processes in different continents that were largely or completely independent of each other. Our information on warfare in pre-Columbian South America comes primarily from three sources: archaeology, ethnohistory (that is, indigenous peoples' own historiography), and contact period history. The bulk of this information is from the Andes. To make sense of these various kinds of information, it is useful to organize it both regionally and chronologically, as well as in terms of a coherent framework of interpretation. The two macroregional divisions considered here are the Andean area and Amazonia.

The Andean Area

The Andean mountain range that runs along the entire extent of western South America saw the development of many complex societies such as chiefdoms, states, and empires during three and a half millennia before the Europeans arrived. The Spaniards who in 1532 conquered the Inca Empire encountered the

last of these complex indigenous societies. Like its many predecessors, the Inca state can be understood as an attempt to control the resources, human labor, and flows of goods in the central Andean area. The varied geography of the region had for thousands of years stimulated trade between the arid coast, the mountains, and the tropical rainforests in the eastern lowlands. Attempts to politically control such trade through military means can be traced in northern Peru to the Initial Period of pottery use (1800–800 BCE). A powerful theocratic state based in the Casma valley on the north coast appears to have maintained trade relations with the north-central highlands and the tropical forest areas beyond. Toward the end of the Initial Period, the Casma polity collapsed, and the area was invaded by its former trading partners in the highlands, associated with the site of Chavín de Huántar on the upper Marañón River on the eastern slope of the Andes. This initiated the first of three major pre-Columbian attempts by highland societies to take advantage of their middleman position between coast and jungle to gain political power. The carved monoliths at Cerro Sechín, a ceremonial center from this period in the Casma valley, show armed men and their dismembered victims, indicating an emphasis on violence, but we do not know if they represent war scenes or ritual sacrifice. As sites in this period are not fortified, it appears that social integration was achieved more by economic and ritual means than by violent coercion.

During the Early Horizon (800–200 BCE), the highland Chavín polity exerted influence over much of Peru. The traditional view is that the widespread distribution of Chavín art designs reflects a religious cult that spread by peaceful means, but defensive

Stone wall, Sacsayhuaman Incan ruins in modern-day Cuzco, Peru. The cliff-side location of this structure would have provided excellent protection against invaders. Photo by Kevin Connors (www.morguefile.com).

fortifications on the north coast suggest that military confrontations also occurred. Conflicts may have arisen regarding control of trans-Andean trade routes conveying Ecuadorian *Spondylus* shell and tropical forest produce, or of coca-producing zones, following a pattern known from later periods. Trophy heads appear not only on north coast pottery, but also on chavinoid Paracas textiles on the south coast and in the art of Pukara in the Titicaca basin. Skull fractures indicating blows to the head occur among the mummies at Paracas. The Chavín interaction sphere began to disintegrate in the third century BCE.

In the Early Intermediate Period (200 BCE–600 CE) the decidedly more militaristic Moche state controlled much of the north coast and built heavy fortifications against a highland polity based at Cajamarca. Such defensive architecture typically consisted of hilltop bastions with walls, moats, and stores of sling stones, but as they lacked water they appear to have been built as protection against brief raids rather than long-term sieges. Trophy heads occur on Moche ornaments, and the pottery shows many realistic war scenes, with warriors in helmets with maces and shields, and the sacrifice of prisoners. Recuay pottery from the adjacent highlands also shows warriors with clubs, shields, or trophy heads. Moche expansion relied on a mixture of military conquest and voluntary conversion of local chiefs, a pattern that continues through later expansions including the Inca. Prestigious older polities were sometimes incorporated peacefully by

indirect rule. Examples of this include the Casma area within the Moche state and the oracle of Pachacamac on the central coast, venerated throughout its existence up until the arrival of the Spaniards. On the south coast, Nazca pottery shows trophy heads and later also militaristic motifs, but the area seems not to have been subjected to centralized state rule. Toward the end of the period, the expansion of the Tiwanaku polity in the Titicaca basin shows little direct indication of military conquest, but there is evidence of human sacrifice and the taking of subject peoples' sacred objects. In northwest Argentina, warriors and trophy heads appear as artistic themes at this time.

In the Middle Horizon (600–1000 CE), a short-lived but powerful state based at Wari in the Mantaro basin, in the south-central highlands, seems to have controlled the south and central coasts in their entirety and almost all of the Peruvian highlands from the city of Pikillaqta in the south to Cajamarca in the north. Like its southern counterpart Tiwanaku, Wari based much of its power at the periphery of its domain on dispersed administrative centers that regularly hosted ceremonial feasts for local leaders. Although some sites suggest a military presence, such as on the boundary of Tiwanaku in the southern highlands, relations with earlier polities in the northern highlands and on the coast show little evidence of militarism. As in earlier periods, however, there is evidence of human sacrifice and ritual decapitation. During this period, the Moche state declined and shifted its capital farther north. The Wari Empire collapsed around 800 CE and Tiwanaku about two centuries later.

In the Late Intermediate Period (1000–1476 CE), the collapse of Wari and Tiwanaku left smaller polities warring with their neighbors throughout southern and central Peru. One of these was the emergent Inca state based in the Cuzco valley on the southern boundary of the former Wari Empire. The endemic warfare called for militaristic leadership in Cuzco as elsewhere. Most archaeological sites from this period are fortified or located on easily defensible hilltops. Coastal and highland groups in central Peru fought over access to the best coca-producing lands at intermediate elevations. In the north, the old Moche state

revived as the expansive coastal empire of Chimor (or Chimú), based at the metropolis of Chan Chan. Like earlier north coast polities, Chimor controlled the crucial maritime trade in *Spondylus* shell from Ecuador.

In the Late Horizon (1476–1532 CE), the Inca state expanded through a combination of diplomacy and militarism to create an empire stretching from Ecuador to central Chile. The military history of this expansion has been reconstructed in some detail, thanks to native Quechua historiography recorded by sixteenth-century Spanish chroniclers and to archaeology. Over the course of less than a century, the Inca were able to assimilate or subdue hundreds of states, chiefdoms, and ethnic groups, including the old kingdoms of the Titicaca Basin, the Chanka and Wanka polities of the Wari heartland, the empire of Chimor, and finally even most of modern Ecuador, the source of the prestigious *Spondylus* shell. Further expansion failed when Inca armies faced simpler but warlike societies in unfavorable environments in northern Ecuador, the eastern lowlands, Argentina (Chiriguano), and central Chile (Mapuche). On the frontier in northern Ecuador, the Inca used fortresses from earlier polities in the area, while on the southeast frontier in Argentina they built a series of new fortresses to stave off attacks from the Chaco tribes. When Francisco Pizarro (c. 1475–1541) and his 260 Spanish soldiers arrived, the Inca Empire was divided by a civil war between two sons of the former emperor, of which the victorious Atawallpa, destined to be executed by Pizarro in 1533, was based at Quito. Building on native narratives, the chroniclers' accounts of this civil war, battle by battle, are the most detailed description of pre-Columbian warfare in existence. Recruitment to Inca armies was by a general draft apparently aligned with the decimal administrative system, which divided the population into groups of ten, one hundred, and so on. Weapons included slings, bows and arrows, bolas, spears, spear-throwers, lances, axes, and bludgeons. Armor and shields were also used.

Some general conclusions on the occurrence of warfare in the pre-Columbian Andes can be drawn. There seems to have been a distinctly Andean tradition of diplomacy through voluntary conversion and indirect rule that, in many cases, offered means of control other than military conquest. In the periods we call horizons, when large parts of the area were well integrated ideologically, whether or not this was achieved with the aid of military force, there was comparatively little warfare, except at the borders of the unified territories. In the intermediate periods, following the disintegration of such polities, there was much more conflict between different local populations and ethnic groups. Conflicts often seem to have involved rivalry over the control of strategic resources or trade routes. The emergence of new power centers generally occurred on the periphery of previous polities, challenging older centers and contributing to their decline. Warfare, like the nonviolent practice of power it complemented, was always embedded in religious or symbolic meanings and often had a ritual aspect, such as head-hunting and human sacrifice. This is evident even in the Inca period, for instance from accounts of divination and sacrifice in preparation for battle, and from reports that the skins of defeated enemies (e.g., defiant Kañari warlords from Ecuador or rebellious lords from the Titicaca area) could be fashioned into drums played at festivals, and their skulls into drinking cups. The obsession with ritualized warfare, human sacrifice, and cannibalism that has been attributed to the Chibcha-speaking chiefdoms of the Colombian Andes probably had much in common with early instances of theocratic warfare in the central Andes.

Amazonia

Our relative lack of information on pre-Columbian warfare in Amazonia is due partly to the very much poorer archaeological record, owing to the tropical climate and the dominance of organic materials in the material culture of Amazonian groups, and partly to the fact that the social fabric of the region was

Force, and fraud, are in war the two cardinal virtues. • **Thomas Hobbes (1588–1679)**

fundamentally transformed by European epidemics for over a century before the arrival of potential chroniclers. The little information that we have includes archaeological discoveries of defensive ditches around villages on the Río Negro and the upper Xingú River, and the eyewitness account, written by the friar Gaspar de Carvajál in 1542, of an unintentional expedition down the Amazon from Ecuador to the Atlantic which at various points encountered flotillas of canoes laden with warriors or riverbank armies equipped with spears, shields, bows and arrows, or blowguns with poisoned darts. Historical and ethnographical data can probably be used to make some inferences about pre-Columbian patterns, but they remain uncertain. From the first millennium BCE, Arawak-speaking peoples inhabited much of the fertile floodplains and the wet savannas from Orinoco in Venezuela to the Llanos de Mojos in Bolivia. Many of these societies were populous chiefdoms engaged in riverine trade and intensive agriculture. The Arawaks are to this day unusual in prohibiting endo-warfare (war among themselves), which is quite common in other linguistic families. The floodplain societies were the first to succumb to European epidemics and slave raids. Linguistic groups such as Caribs and Tupí have been described as warlike and prone to cannibalism, but it is hard to say how much of the warfare observed by early Europeans in the region was a response to upheavals following their arrival, as decimated and enfeebled riverine groups were subjected to systematic predation by previously marginal groups. The ideology of predation that has been posited as common to most Amazonian Indians, and as generative of endemic warfare and ritual cannibalism, probably has pre-Columbian roots but may have been exacerbated during the colonial period. Feuding among simpler groups has commonly involved raiding for women (bride capture), head-hunting, and accusations of sorcery, whereas the more complex pre-Columbian chiefdoms would have competed over floodplain areas and trade in prestige goods such as metal objects from the Andes. Carvajál reports that the Tupí-speaking Omagua on the upper Amazon took prisoners of war

from inland groups, keeping some as slaves and taking head trophies from others. He also notes that they had spear-throwers with gold and silver inlays, which were probably of Andean origin.

In sum, warfare generally had quite different cultural meanings to the indigenous South Americans and to the European conquistadors of the sixteenth century, which in part explains the incapacity of the former to resist the latter. On the other hand, it seems generally possible to relate the occurrence of warfare to similar kinds of historical processes, for instance the struggle to control important resources or trade routes, and the shifting balance of power between centers and peripheries in regional or global systems of exchange.

Warfare— South Asia

South Asia's first recorded civilization utilized citadels and walled cities almost five thousand years ago, indicating a need for military protection. Warfare has been a constant in its history ever since, whether states fought to establish regional empires or foreign armies invaded to colonize. The region may not have achieved political stability yet; India and Pakistan have fought four wars since being partitioned from British India in 1947.

Throughout most of its long history, South Asia has consisted of a multitude of states, all vying against one another for power, territory, and domination. At times, certain states have expanded outward from their core areas to form India-wide or regional empires, such as the Maurya Empire (c. 324–c. 200 BCE), the Cola Empire (850–1279 CE), or Vijayanagara (c. 1346–1565 CE). South Asian empires have also been erected by foreign invaders, as in the case of the dynasties of the Delhi sultanate (1192–1526), the Mughal Empire (1526–1857), and the British (c. 1850–1947). All these contests have involved warfare.

2600 BCE–1720s CE

Very little is known of the military aspects of the first recorded South Asian civilization—the Harappan civilization (c. 2500–1900 BCE)—since its script has not yet been deciphered. That it possessed citadels and walled cities seems to indicate a need for military protection. The Harappans had rudimentary bronze weaponry, mostly swords, spearheads, and arrowheads. Most probably, their enemies were not formidable in terms of either ability or numbers. Although

it was initially thought that the Harappan civilization was destroyed by the invading Indo-Aryan tribes, current research posits that environmental factors caused its demise around 1900 BCE.

The Coming of the Indo-Aryans

From about 1500 BCE, seminomadic, pastoralist, and Sanskrit-speaking Aryan tribespeople began penetrating South Asia from the northwest. Although they possessed sophisticated military technology in the form of the light two-wheeled war chariot, the incoming Aryans were not a disciplined army led by a great leader on a campaign of swift conquest. Indeed, the Aryan “conquest” was more of a migration, measured in generations rather than in years. The numerous Aryan tribes—about forty are mentioned in the Rig Veda, a sacred text dating from the second millennium BCE, if not earlier—were not peaceful. They were in constant conflict with one another, mostly over cattle, which was how they measured relative wealth and power. (The ancient Sanskrit word for *fighting* literally means “to search for cows.”) The mythical conflict between the Kauravas and the Pandavas, which forms the central narrative of the epic *Mahabharata*, has a factual kernel, probably originating as a tribal war over cattle and land in what is now northern Punjab.

When not fighting amongst themselves, the Aryan tribes fought the indigenous Dasas. We know that the Dasas had many forts, because the Rig Veda often refers to Indra, the main Aryan god, as Purandaradasa—“destroyer of the Dasa forts.” Dasa forts may well have been wooden, for Aryan hymns often call upon Agni, the fire god, to help defeat the Dasas. In the

Rig Veda, a war between two Aryan tribal groupings was won by a King Sudasa, whose name indicates that some Dasas had already been assimilated into Aryan culture. Evidence of Aryan attempts to invade and settle peninsular India is contained in the other great Indian epic, the *Ramayana*, which tells the story of the Aryan Prince Rama's expedition to Lanka (Sri Lanka) to rescue his wife Sita, who has been abducted by the evil demon king, Ravana. Rama was aided by the monkey-god Hanuman; some see in Hanuman and his people a reference to the aboriginal tribes or the Dravidian peoples of southern India.

By 500 BCE, the mixing of the Aryan and indigenous peoples had resulted in the distinctive *varna* (caste) social pattern, which most resembled the estates or orders of medieval Europe, and set the template for what became Hinduism. Here, the second-ranking Kshatriyas were the *varna* of warriors and kings. Yet, throughout the traditional period, considerable social mobility existed, especially in warfare. Lower *varna* men fought in the Mauryan armies, alongside charioteers and elephants, and by the eleventh century, it was not uncommon for men from the lowest Vaishya (merchant) or Shudra (labourer) *varnas* to assume Kshatriya or Rajput (literally, "son of a king") status through military service. Indian peasantry supplemented their agrarian incomes by soldiering, which was seen as an honorable profession. A military labor market, mediated by military entrepreneurs known as Jama'dars, became a feature of precolonial India.

Magadha and the Maurya Empire

Kingdoms had developed on the Gangetic plain by 500 BCE. One of these, Magadha, straddling the Ganges River in modern-day Bihar, was responsible for introducing the war elephant into South Asian warfare. Elephants soon became as important as chariots in South Asian warfare. Besides becoming the traditional mount of rajas, elephants were used to trample and slaughter enemy troops, batter down enemy forts, for transport, and as archery platforms. But elephants were expensive and difficult to maintain, and only the richer Indian polities could afford large numbers of

them. Archery was also well developed by 500 BCE. Indian archers used double-curved, composite wood-and-horn bows, which had a range of about 100–120 meters. In battle, archers on foot were shielded by a rank of javelin-armed infantry. The absence of swift horses in South Asia resulted in the transformation of the two-wheeled chariot into the four-wheeled armored chariot carrying many more archers. Thus, though their offensive power increased, their battlefield mobility was impeded. Magadha also developed the catapult.

Magadha became the basis for the Maurya Empire (c. 324–c. 200 BCE), during which time the *Arthashastra*, a classic work of Indian statecraft that adopted an amoral, realist approach to war and diplomacy, appeared. Reputedly authored by the philosopher and imperial adviser Kautilya (flourished 300 BCE), it included details on military organization, strategy, tactics, and logistics, and stressed the value of effective espionage and bribery. That the Mughal emperor Aurangzeb (1618–1707; reigned 1658–1707) wanted to abolish the special fund for bribing enemy forts, and that the British under Robert Clive (1725–1774) defeated the forces of the nawab (provincial governor) of Bengal at Palasi (1757) through bribery demonstrates the remarkable continuity of Kautilyan strategies.

Campaigns

Throughout this period, campaigns of the Indian empires, both north and south, were essentially similar. Armies were moving cities, complete with large bazaars to handle supply. War elephants were the most important component until about 1100 CE. They were displaced by the heavy cavalry of the Muslim invaders, who reintroduced the stirrup—originally invented in South Asia in the first century—to warfare there. The stirrup, by anchoring the rider firmly to the horse, made cavalry a true shock weapon, and more useful than elephants in battle.

Siege engines, and after about 1350, large bombards and cannon—which required industrial and financial capacity that only the large empires could sustain—were highly unwieldy, requiring

Tulsi (the elder) and Jagjivan, *Battle Scene with Boats on the Ganges* (1590–1595). Opaque watercolour and gold on paper. Collection Victoria and Albert Museum.

hundreds of pack oxen. This meant that the progress of an imperial army was painfully slow, about 8 kilometers per day even in Mughal times. Given the nine-month-long, monsoon-delimited campaigning season, an imperial army's typical reach was between 1,080 and 1,200 kilometers. Campaigns were also slowed by the nature of the frontiers, which were imprecise bands of territory between two core areas, inhabited by petty rajas who would either have to be co-opted or subdued before the invading army could proceed. Battles were short and confused affairs, the onus being on individual heroic prowess rather than

on disciplined maneuver. If a king or commander were killed or captured, then as in *chaturanga*, the precursor to chess that was popular among members of the Kshatriya class, his army was considered defeated.

Traditional Indic warfare was land based. The only exception to this was the Colas, who, under Rajaraja I (reigned 985–1014) and his successor Rajendra I (reigned 1014–1044), took to the sea to conquer Sri Lanka and Srivijaya (an empire located on the islands of Sumatra and Java). The strategic vision impelling these seaborne campaigns was the control of South-east Asian maritime trade.

The Mansabdari System

Traditional Indic polities were segmentary, essentially “military confederation[s] of many chieftains cooperating under the leadership of the biggest among them” (Stein 1980, 55). Loyalty was a problem. The Mughals met this challenge with the *mansabdari* system, which entailed granting a specified rank to a noble and entitling the noble to revenue from an assigned area of land. *Mansabdari* ranks carried with them the duty to provide a specified number of cavalrymen for battle. A rank was not hereditary, however, and could be revoked at the emperor’s pleasure. The *mansabdari* system was an early attempt at creating military professionalism in India.

Colonial Warfare, 1720–1947

European penetration of India, which had far-reaching military consequences, began in the 1600s, with the appearance of European trading companies on India’s shores. Initially, the armed forces of the main contenders—the English and the French East India companies—were not a serious threat. But by the 1720s the French, balking at the high cost and low survivability of European soldiery in Asia, were recruiting Indian musketeers, whom they called *sepoys*, after the Persian word *spahi* (soldier), and training them in the latest European tactical doctrine of close-order drill and volley firing. Battles such as Adyar River in 1746 and Buxar in 1764 proved that small sepoy detachments could defeat much larger Indian hosts. The British copied the French, and both countries took advantage of the political flux resulting from the Mughal Empire’s decline to become players in South Asian geopolitics.

The English proved more successful at this, defeating the French twice (1744–1748 and 1749–1754). They then turned their attention to defeating the Indian polities, winning wars against Mysore (1767–1769, 1780–1784, 1790–1792, 1799), the Marathas (1775–1782, 1803–1805, 1817–1818), the Gurkhas (1814–1816), and the Sikhs (1845–1846, 1848–1849). Each of these wars resulted in

the widening of the English East India Company’s (EIC’s) territory. The Marathas and the Sikhs were formidable foes who adopted Western tactics and weaponry. To fight them, the EIC tapped into the military labor market to vastly increase the size of their land forces. By 1796 these numbered 57,000 sepoys, bolstered by an additional 13,000 British troops; by 1856 there were 226,352 sepoys and 38,502 British troops. These were distributed amongst the three “presidency” armies of Bengal, Bombay (now Mumbai), and Madras. These armies only cooperated during wartime; otherwise they were fairly autonomous. This autonomy extended to recruitment. While the Bombay and Madras armies recruited Indians of many communities and castes, the Bengal army, which was also the largest, increasingly recruited Brahmans (that is, people of the highest-status *varna*) of the Gangetic heartland. The EIC ensured that sepoy wages were regularly paid, in contrast to the rather haphazard arrangements obtained in the Indian polities. This increased the incentive for Indians to become EIC sepoys. The EIC state financed its land forces by resorting to military fiscalism: it used its army to accrue territory, the revenue from which was used to finance its army.

The Uprising of 1857–1858

By the mid-nineteenth century, sepoy units were commanded by British officers, with a subordinate Indian officer class acting as a crucial liaison between the British officer and the Indian private soldiers, but effectively barred from higher command. In 1857 the Bengal Army’s Hindu and Muslim sepoys rose up against their British officers. The mutiny was sparked by the fears of the sepoys that the British were conspiring to make them transgress their religion through the introduction of new weaponry lubricated with animal fat, which was forbidden by religious law to both Hindus and Muslims. But the military mutiny quickly became a generalized revolt against the EIC. Cantonment (garrison) towns such as Lucknow and Kanpur

became centers of revolt, as did the old imperial city of Delhi, where sepoys gathered with vague ideas of restoring the Mughal Empire. The heavily outnumbered British were caught completely off guard. Had the mutinous sepoys attacked Calcutta (Kolkata), the capital of British India, they might have won. As it was, the British were able to rally, relying on Punjabi sepoys and on reinforcements that arrived by sea. That quelling the uprising took a full two years speaks to its seriousness and to the military prowess of the Indian leaders such as Rani (Queen) Lakshmi Bai (1835–1858) of Jhansi, and Tantia Topi (c. 1819–1859).

After the “Mutiny,” as the British termed it, the British Crown took over the Indian army. Measures were undertaken to prevent another mutiny. The ratio of British to Indian troops was set at one to three, and recruitment, even in the Bombay and Madras armies, was focused more towards the northwest. The Indian military was thus separated from Indian society. British authorities justified this on the basis of the “martial races” ideology, a mixture of practical concerns and Victorian ethnography, which held that in India, “only certain clans and classes...[had]...the physical courage necessary for the warrior” (MacMunn 1911, 129). These “martial races” included Sikhs, “Punjabi Musalmans” and Nepali Gurkhas. To further ensure against mutinies, the ethnic composition of army units was strictly monitored.

South Asian Forces Abroad

During the late nineteenth century, South Asian warfare centered on the Indo-Afghan frontier, the scene of the “Great Game,” a rivalry between the Russian and British empires. Over twenty campaigns and the Second Afghan War (1878–1880) were fought in largely fruitless attempts to control the area’s tribes. During this time the cost of the Indian army, which amounted to about 30 percent of the Indian budget, was entirely borne by Indians. Indian forces also participated in military efforts in many parts of the British Empire, mainly in Africa and Asia.

This overseas deployment was greatly increased during World War I (1914–1918), in which India, as a British imperial possession, was committed to the Allies. The unified Indian army’s Meerut and Lahore divisions, as Britain’s strategic reserve, were deployed on the western front (France) in 1914–1915. Sepoys also saw action in the disastrous Mesopotamian campaign (1915–1916), in east Africa (1915–1918), and in Palestine (1917–1918). The prospect of fighting their Ottoman coreligionists caused Muslim sepoys at Singapore to mutiny in 1915. Sepoy recruitment skyrocketed, reaching ten thousand men a month by 1915. By 1918 India had recruited 1.4 million men for the Allied war effort, many from classes previously deemed “unmartial.” In 1917 Indians were allowed into the Indian army’s officer corps, which had, until then, been “...properly reserved for the governing race” (Sundaram 2002, 75).

After World War I, the army reverted to its frontier warfare role. It was also used to disperse Indian nationalist disturbances, most notoriously at Amritsar in 1919. Some sepoys’ refusal to fire on nationalist demonstrators at Meerut in 1930 indicates that they were becoming nationalist themselves. This period also witnessed the setting up of officer training for Indians in India itself. The British strongly preferred “martial-race” Indians (such as Sikhs and Punjabi Muslims) as officers, and posted them to only 7.5 percent of the army.

During World War II the Indian army again ballooned—to 2.2 million men—and men from nonmartial groups were recruited in increasing numbers, though Indian nationalists resented being once again dragged into war without being consulted. Though the Indian army fought in the North African and Italian campaigns, its most significant deployments were in Malaya in 1941–1942 and in Myanmar (Burma) in 1941–1945. Malaya was a harsh battleground for the Indian army, which was ill-trained and ill-equipped for jungle warfare; forty-five thousand Indian *jawans* (soldiers) were captured by the Japanese. Out of this group was formed the Indian National Army (INA), a force allied to the Japanese,

whose aim was to gain Indian independence from Britain. Though not a significant military threat, the very existence of such a force was further proof of the upwelling of nationalist feelings in the military, and of the fact that, once the war was over, *jawans* would not stand for continued British rule. After shattering defeats, the Indian army overhauled itself in 1943–1944, and met and defeated the Japanese invasion of northeastern India in 1944. Whereas in 1939 there were only eleven Indian majors, by 1945, 40 percent of the Army's officers were Indian, and there were Indian brigadiers.

South Asian Warfare since 1947

The partition of British India into the sovereign states of India and Pakistan in 1947 resulted in the partition of the old Indian army, endemic warfare between the two new states (centered mainly around the border area of Kashmir), and differing models of civil-military relations. Broadly, the army was divided on a two-to-one ratio, with two units going to India for every one going to Pakistan. Partition gave Pakistan most of the cantonments and training facilities, but it gave India the war industries. Between 1947 and 1999, India and Pakistan fought four wars, one of which, in 1971, led to the independence of East Pakistan as the nation of Bangladesh. Two of the wars have been stalemates and two have been Indian victories. These wars have been short, reflecting the immense cost of modern warfare for developing countries. Insurgency still continues in Kashmir, which has been unofficially partitioned. Though the military officers of both countries are still mostly drawn from the "martial races," their civil-military relations are radically different. Whereas the Indian military has been effectively subordinated to the civilian democratic government, Pakistan has been subjected to long periods of military rule (1958–1972, 1977–1988; 1998–2007). Though both countries now possess nuclear weapons, India is reasonably stable. Pakistan, however, is being assailed by the Taliban on one side, and its own army's Inter-Services-Intelligence agency on the other, and it is

dangerously close to becoming a failed state, which could threaten the stability and security of the entire region.

Warfare— Southeast Asia

Indigenous warfare has been an important component of Southeast Asian society. Methods of warfare changed and improved over time, as did the purpose of armed conflict, whether religious, political, or social. Warfare in Southeast Asia depended more on attaining booty and political objectives, and less on expanding territory and disseminating culture.

Before foreign intervention and the introduction of firearms to Southeast Asian societies in the fifteenth and sixteenth centuries, headhunting was a prevalent form of conflict both on the mainland and in archipelagic Southeast Asia. Headhunting raids allowed male warriors to prove their manhood and indicate preparation for marriage. Failure in these raids was considered a disgrace and damaged men's social status. Armed conflict was carried out in the context of ceremonies to honor and glorify ancestors and spirits. Religion was a justification for warfare as well. Buddhism was active in Southeast Asian societies, and Buddhist leaders waged war whenever there was a threat from competing religions or whenever they felt that the religion's influence was declining.

Interpretations of Warfare

European nations that established a commercial presence in Southeast Asia during the fifteenth and sixteenth centuries viewed warfare differently from the indigenous inhabitants. The Vietnamese considered war as a means to an end, but the end was the attainment of material goods and war captives for human labor purposes, not territorial ambition.

Similarly, on the islands of Bali and Java, prisoners of war were used as slaves and exported between 1650 and 1830. This was a common feature of warfare in most Southeast Asian countries. The objective was booty and political control and not territorial ambition or diffusion of civilization. One sought to control an enemy capital and its nearby communities to secure material and human resources rather than to change individuals' ways of life.

Between 1407 and 1427, Ming China defeated Vietnam and occupied the country, including its capital, Hanoi. The Vietnamese studied the advanced military techniques and the bureaucracy and government of the Ming. Eventually the Vietnamese drove out the Chinese, but as a result of Ming influence, the Vietnamese came to believe—as the Ming Chinese did—that war should be used to civilize barbarous cultures. The Vietnamese used force against their southern and northern neighbors, the Chams and Tai. Exploration of new lands and their annexation were further justifications for warfare that the Vietnamese and other Southeast Asian civilizations slowly adopted.

The tactical use of terrain in combat was critical in waging conflict. Vietnamese armies used the terrain to achieve success on the battlefield during their wars against the Chams and Tai. In campaigns against the Chams, Vietnamese commanders relied on amphibious assaults and regular troop movements on flat coastal areas. Against the Tai, who occupied valleys and mountain regions, Vietnamese armies conducted quick strikes and flanking movements in order to avoid becoming trapped and isolated in the mountains.

Y. Pranishnikoff, *Military Cadets of Tonquin, North Indochina* (1899). The Chinese relinquished rights to French-occupied Tonquin (now Tonkin, Vietnam) in 1875; it became part of French Indochina in 1887. New York Public Library.

Foreign Influence and Methods of War

European and Chinese governments occupied and dominated parts of Southeast Asia as far back as the fifteenth century. They brought with them new weapons that altered indigenous warfare. Firearms, although not common, were available by the fifteenth century from both sources and allowed Southeast Asian societies allied to the Europeans or Chinese to subdue their less well-equipped neighbors. Bows, arrows, lances, blowpipes, and animals such as horses and elephants were gradually replaced with cannons and muskets. Kingdoms in Malaysia and Indonesia retained traditional weapons while adopting new ones in order to maintain tradition. Firearms were mythologized in a positive manner.

Twentieth-century warfare in Southeast Asia saw a new concept emerge. Guerrilla and protracted conflict was prevalent as a means to defeat imperialism and

enhance nationalist sentiment. Filipino rebels made use of guerrilla raids against U.S. troops during the early 1900s but were eventually conquered. During the Japanese occupation of China and Southeast Asia in the 1930s and 1940s, Chinese nationalists and rebels used guerrilla tactics and foreign aid from the West to achieve victory and end foreign domination. Guerrilla warfare flourished during the Cold War as indigenous Communist forces attempted to unify their countries under a Soviet brand of Communism or their own style of socialist government.

The Vietnamese defeat of the French at Dien Bien Phu in 1954 and their eventual strategic victory over the United States in the Vietnam War (1959–1975) showed how successful guerrilla warfare and manipulation of public opinion could be in overthrowing foreign domination. The involvement of the United States in Vietnam introduced changes in the conduct of war and foreign affairs in general. Now the consensus is that nations should have clear objectives, a popular

base of support, approval from the world community, and credibility if they are to wage a war successfully.

Terrorist activities by Islamic fundamentalists in the late 1990s and into the early twenty-first century have continued the earlier trend toward guerrilla warfare and protracted conflict. Western powers such as the United States continue to support, either directly or indirectly, low-level warfare against those deemed terrorists or insurgents.

Warfare— Steppe Nomads

The nomadic pastoralists of the Central Asian steppes played a major role in Eurasian warfare from nearly six thousand years ago until the early eighteenth century. Their wars, internal and external, shaped patterns of politics, trade, and cultural exchange throughout the Eurasian world, and they produced some of the most successful and fearsome conquerors world history has known.

The foundation of nomadic military interaction with, and success against, their sedentary neighbors was the geography of the steppes. A vast sea of grass stretching from the northwest frontiers of China to north of the Black Sea, with an extension into modern Hungary, the steppes are too dry for traditional methods of agriculture: rainfall is insufficient and the rivers too unreliable for irrigation. But the grasses of the plains can support vast herds of grazing animals, and these formed the basis for the nomad's pastoral mode of subsistence. Cattle, sheep, and goats provided meat, milk, skins, and wool for clothing and shelter; animal bones and tendons were used in constructing tents and above all in the manufacture of the composite recurved bow that was the nomads' main weapon in hunting, herding, and war. One other animal held the key to nomadic efficiency in herding and combat: the horse. Horses were apparently first domesticated in the area north of the Black Sea as long as six thousand years ago; they and the oxen that drew the carts that carried the nomads' tents and possessions let entire peoples migrate from summer to winter grazing lands and to entirely new lands in response to outside pressures. Horses also gave steppe armies tremendous tactical and strategic mobility.

Mobility and firepower, wielded by people accustomed to constant travel, camping, occasional short rations, and periodic violent competition with other nomads for the best grazing land—that is, accustomed to constant military campaigning as a lifestyle rather than as an aberration from settled life—gave nomadic peoples significant military potential vis-à-vis their sedentary agriculturalist neighbors outside the steppes. At the same time, the limitations of pastoralism necessitated at least indirect contact with sedentary populations: nomads needed at least a few agricultural products to supplement their diet. They also desired certain products, most importantly cloth and metal implements, whose fixed capital requirements for production made them difficult for nomadic peoples to produce. Thus nomadic peoples tended to get what they wanted from agricultural societies by trading, raiding, tribute (bribes to deter raids), or conquest. This was the fundamental economic backdrop to steppe nomads' warfare with people beyond the steppes.

Geography and State Formation

Nomadic warfare was in the first instance intertribal, aimed at other nomads in competition for grazing lands, as mentioned earlier. Because the pastoral way of life supports a far less-dense population than agriculture, individual tribes could rarely muster sufficient manpower to pose a serious threat to sedentary states. Hindered by their meager surplus wealth and scattered population base, steppe peoples rarely generated political formations more complex than individual tribes. The paradoxical result was that nomadic coalitions (and therefore the nomadic

military threat) were most likely in close proximity to rich settled states. Trading and small-scale raiding along the border might generate a sufficient flow of prestige goods to a successful steppe leader to allow him to build a larger coalition of tribes through a combination of alliances built on gifts and intimidation of others based on those alliances. This larger coalition's army could then extract a larger flow of goods from the sedentary state (and could draw attention from sedentary armies, increasing the pressure for defensive cooperation), allowing the coalition to grow, and so on. Large coalitions subsumed, at least for a time, their constituent tribes into chiefdoms and at least once, under the Mongols, into a fully fledged nomadic state, though such coalition chiefdoms tended to be fragile and to break up in the face of serious reverses or succession crises. Thus warfare and strong war leaders were crucial to state formation on the steppes.

Another aspect of steppe geography tended to concentrate such state formation at the eastern end of the steppe. Here the Mongolian plain abutted the northwest frontier of the Chinese civilization, which from the second century BCE was consistently organized into a rich and periodically aggressive state. In addition, migration of hunter-gatherers from the forests and tundra to the north generated new tribes and pressures more intensely here than farther west. The largest and most powerful nomadic coalitions therefore tended to arise here. Losers (either internally or in conflicts with China) were pushed westward, generating the east-to-west migrations that usually characterized steppe populations and that sometimes became nomadic incursions into settled lands at the outlets of the steppes into Persia and Europe. If the Silk Roads across the steppes connected Eurasia commercially, then the pressures of warfare and state formation on the steppes connected Eurasia militarily.

Nomadic Warfare: Tactics and Strategy

The tactical effectiveness of nomadic warfare was based in the first instance, as noted above, on the

combination of mobility and firepower that horses and composite bows gave to steppe peoples. In the hands of a practiced archer, the bow, a short but powerful weapon made from a combination of wood, horn, and sinew glued together and strung against its natural curve, could send light arrows several hundred yards with some accuracy or direct heavier arrows over shorter ranges with dangerous penetrating power. Nomadic horse archers were skilled at harassing enemy formations from a distance, retreating when counterattacks were launched, only to return to the attack when the enemy advance became scattered or disorganized. Feigned flights were thus a standard part of the nomadic tactical repertoire. Elite nomadic warriors—tribal nobles and the favored forces of larger coalitions—often wore armor that included some sewn-on metal plates and was heavier than the leather and raw silk protection worn by regular horse-riding archers; the elite forces also wielded lances and even swords. This heavier element in nomadic armies could engage in hand-to-hand combat, delivering a decisive charge against an enemy softened up by archery. Nomadic armies often drew up for battle in a broad, shallow crescent formation, the wings thrown forward with the aim of encircling the enemy flanks. But flexibility was the key nomadic strength in combat, as they used their mobility to create chances to “herd and cull” the formations of sedentary armies using the skills they practiced on mass animal hunts on the steppes.

Still, in the right terrain and under competent leadership, sedentary armies could sometimes defeat nomadic forces in battle, using their often superior weight of armor, weaponry, and numbers to break nomadic lines in hand-to-hand fighting.

What increased the challenge posed by nomadic forces was their operational mobility and above all their strategic trump card: their base in the steppes. The armies of sedentary states, which inevitably included large numbers of infantry, could not hope to keep up with the purely cavalry forces of the steppes: the latter could outrun pursuit and avoid battle when it suited their purposes, raiding and withdrawing before

opposition could arrive on the scene. The Mongols deployed this advantage offensively, using their efficient communication system to bring several units to a battlefield from different directions, often inducing panic in their enemies and giving them the impression of being surrounded by “hordes” far larger than they in fact were (the Mongols, like other nomads, often fought outnumbered against sedentary armies). But mobility was most useful defensively, in combination with the logistics of steppe warfare. When threatened by superior forces, nomadic forces could simply withdraw onto the steppes. It was very difficult for a large infantry army to follow them into this terrain because the land could not support armies that lived on grain supplies. Carting supplies in was both prohibitively expensive and subject to severe range restrictions, as the oxen or horses used to pull carts of food also had to be fed. Thus, beyond perhaps a four days’ march from a supply depot, even armies with large supply trains ran out of food—never mind that water supplies were also often problematic. Attempts to push beyond this limitation consistently ended in disaster. For four and a half millennia, consequently, steppe nomads raided and conquered from a base itself immune to conquest except by other nomads. Because nomadic strategy and tactics were so firmly based in the nomadic lifestyle, sedentary generals could not adopt them easily. Adoption of nomadic techniques therefore usually required use of nomadic allies by sedentary states, an arrangement that carried its own dangers.

Given this immunity, the military measures sedentary states took against nomadic threats often centered on various forms of fortifications, since the major weakness of most nomadic armies (the Mongols being a partial exception) was, inevitably, siege warfare. Not only were city fortifications built up on the steppe frontier, but some states built larger systems of fortification such as the various walls that came to form the Great Wall of China. These were designed less to keep the nomads out (virtually an impossibility) than to slow them on their advance and return from a raid, thereby allowing a defensive force to

bring them to battle. But fortifications were also expensive.

Cycles of Nomadic Military History

The relationship that developed between nomadic peoples and their sedentary neighbors as a result of these military dynamics tended to follow a cyclical pattern. Small-scale raiding and trading resulted in both increasing acculturation of the nomads to the political norms of the sedentary society and increasing political organization on the steppes. Both results tended to facilitate large-scale alliance with or conquest of the sedentary state and temporary union of the nomadic and sedentary worlds. But the economic and cultural incompatibility of the two worlds led to renewed split, and the cycle started over. Overall, the long-term trend was toward growth of the sedentary world at the expense of the nomadic world. This was fundamentally a matter of demography: agriculture supported far more people than pastoralism, and the advantage grew over time. But it was also a matter of technology. Gunpowder weapons, in combination with fortifications, paradoxically both contributed to and helped end the last great age of nomadic conquests.

Broadly, the stages of nomadic history may be outlined as follows. A classical age, from the first appearance of nomads such as the Xiongnu in China and the Scythians in the west through the late second century CE, and the decline of the Parthian Empire in the first decades of the third century CE, established the patterns of interaction between the nomadic and sedentary worlds. Between the third century and the twelfth century, larger nomadic coalitions of Uygurs in the east and Turks in the west dominated the steppes, with peaks of invasion and conquest of sedentary areas in the seventh and eleventh centuries. Then in the thirteenth and fourteenth centuries, the Mongols under Chinggis (Genghis) Khan (c. 1160–1227) and his successors created the largest land empire in history. Their extraordinary success rested in part on Chinggis Khan’s remarkable ability to reshape the tribal political structure of nearly the

entire steppe world to his advantage, creating the basis for a longer-lasting nomadic political structure than hitherto. Still, the Mongol Empire fractured among Chinggis's grandsons and then drifted apart as the Mongols acculturated to their conquered populations. Finally, with the spread of gunpowder technology from the fifteenth century (a somewhat ironic result, in part, of the trade connections promoted by the Pax Mongolica), there appeared a set of hybrid states and military forces, including the Ottomans, the Mughals, the Muscovites, and the Manchus, who managed to wed nomadic cavalry forces to cannon and musket-wielding infantry. Though initially this combination facilitated the renewed conquest of vast sedentary areas by nomadic-led forces, it also proved to be the combination that allowed the empires thus created to tame, once and for all, their own nomadic frontiers. By the early eighteenth century, the remaining steppe nomads, hemmed in by fortifications, guns, and co-opted light cavalry forces of nomadic origin, passed out of the realm of military effectiveness for good.

Warsaw Pact

The Warsaw Pact, officially known as the “Treaty of Friendship, Co-Operation, and Mutual Assistance” among the seven socialist states of post-World War II Europe (Poland, Hungary, Czechoslovakia, Romania, Bulgaria, Albania, and the Soviet Union), was the Soviet Union’s most significant multinational military alliance from 1955 until its collapse in 1991.

As the Red Army (later called the Soviet Army) swept through the eastern part of Europe at the end of World War II, it incorporated more than a half million troops from countries in eastern Europe into its forces. By 1949, by which time the Cold War between the Soviet Union and the United States was already well established, the Soviets had concluded bilateral military alliances with each of these Eastern European countries, all of which were by then Communist. The alliances permitted 1 million Soviet troops to remain in the region and subordinated the armed forces of the satellite countries to Soviet military authorities. During the early 1950s the European allies of the United States, seeking to find a way to defend themselves against a possible Soviet attack, decided that they would have to rearm the recently defeated Germany, that is, the newly created Federal Republic of Germany (West Germany). In 1954, after an effort to create a completely European military force failed, the United States joined fifteen other countries to create the North Atlantic Treaty Organization (NATO). To counter this alliance, on 1 May 1955, the Soviets created the Warsaw Treaty Organization (WTO), which is often referred to as the Warsaw Pact, transforming the formerly bilateral alliances into an international organization.

The members of the Warsaw Pact claimed that it was formed in the postwar spirit of creating effective international organizations. In fact, the Soviets made no effort to create a truly cooperative, multinational force. They dealt with their allies primarily in the old bilateral forms, thus inhibiting the possibility of the Eastern Europeans allying among themselves on sensitive issues. While the Soviets devised strategy and designated their own troops as the primary combat units, the Eastern European militaries managed the war games, mobilized forces, or acted as Soviet proxies in furnishing Third World countries with arms. The fundamental strategic plan of the Warsaw Pact, that is, of the Soviet Union, was to achieve a quick victory over NATO forces after any attack. In fact, documents recovered after the collapse of the German Democratic Republic (East Germany) suggest that few people outside of a narrow elite were aware of the details of NATO’s defense in depth, rendering the Warsaw Pact’s strategic plan doubtful at best.

The most serious crises that the pact confronted were the Hungarian Revolution, the Prague Spring, and the Solidarity movement: in 1956, when a serious revolt broke out in Hungary, the Soviets, without consulting their allies, crushed it with 200,000 troops. In 1968, when the Czechoslovak government introduced reforms such as greater freedom of the press, the Soviets reacted by occupying Czechoslovakia with Warsaw Pact forces consisting of twenty-three Soviet divisions supplemented by five Eastern European divisions and a small group from Bulgaria. This preponderance of Soviet forces clearly demonstrated the actual position of the Eastern European allies in the organization, as well as the coercive nature

The outcome of the war is in our hands; the outcome of words is in the council. • **Homer (ninth–eighth? c. BCE)**

of Communist rule in general. In 1981, the Soviets were spared the difficult choice of whether to use WTO forces to invade Poland, where the Solidarity movement was challenging the government, when the Polish leadership itself imposed martial law. These three crises, especially the last two, led to increasing disillusionment among the Eastern European allies. The Romanians did not send any troops to help put down the Prague Spring in 1968 and shortly thereafter insisted that Soviet troops leave their country. Albania, which had already become inactive, completely withdrew in 1968 also. During the 1980s, meetings of the Political Consultative Committee, allegedly the highest organ of the WTO, often provided the increasingly restive Eastern European allies a forum for voicing their views.

In 1989 the sudden and unexpected collapse of Communism in all the Warsaw Pact countries except the Soviet Union quickly made the pact obsolete. When East Germany joined the Federal Republic of Germany, the futility of maintaining the WTO became manifest. On 1 July 1991, Vaclav Havel,

president of Czechoslovakia, declared the Warsaw Treaty Organization dissolved. The fact that Havel was a former dissident lent a peculiar irony to the end of this not particularly effective alliance.

Waste Management

Humans have always created waste. Throughout history it has been left behind, dropped into streets, dumped in waterways, covered with dirt, composted, incinerated, and recycled. Advances have been made globally to confront the complex problems of waste generation, collection, disposal, and materials recovery, but finding a way to manage solid waste in order to preserve resources and minimize pollution is a continuing challenge.

Over the years and around the world, solid waste—garbage, trash, or rubbish—has been abundant, cumbersome, and often polluting. But many factors besides waste itself combine to produce a waste problem, including perception and the conditions under which people live. The greatest refuse-management problems exist in cities. Waste also has social and cultural meaning; what societies retain and what they throw away says a great deal about them and the values they place on material goods.

Before the Industrial Revolution

Humans began abandoning the nomadic life around 10,000 BCE. Tribes that followed game left their wastes behind. In towns and cities such habits could not be tolerated by the citizenry, but methods of dealing effectively with refuse took time. In ancient Troy, food and human wastes were sometimes dropped on the floors of houses or dumped into the streets. When the stench became unbearable, people covered the droppings with a fresh supply of dirt or clay. In the streets, pigs, dogs, birds, and rodents ate the organic material. The debris accumulation in Troy amounted

to about 1.5 meters per century, and as much as 4 meters per century in other cultures.

While the state of sanitation was appalling in many parts of the ancient world, there were some signs of progress. In Mohenjo Daro, founded in the Indus Valley about 2500 BCE, central planning led to the construction of built-in home rubbish chutes and to the institution of scavenger services. In Heracleopolis, founded in Egypt about 2100 BCE, wastes were collected in areas inhabited by the privileged but dumped primarily in the Nile River. About the same time, the homes of the Sea Kings in Crete had bathrooms connected to trunk sewers, and by 1500 BCE the island had land set aside for disposal of garbage.

Religion sometimes was important in enforcing sanitary practices. About 1600 BCE, Moses wrote a sanitary law code under which Jews were expected to bury their waste far from living quarters. The Talmud required that the streets of Jerusalem be washed daily despite the scarcity of water.

In the classical period, waste plagued even the high culture of Athens. About 500 BCE, Greeks organized the first municipal dumps in the Western world, and the Council of Athens began enforcing an ordinance requiring scavengers to dispose of wastes no less than 1.5 kilometers from the city walls. Athens also issued the first known edict against throwing garbage into the streets and established compost pits.

Ancient Mayans in the New World also placed their organic waste in dumps and used broken pottery and stones as fill. Records from second-century BCE China reveal “sanitary police” who were charged with removing animal and human carcasses and “traffic police” responsible for street sweeping.

Ancient Roman public toilets (latrines), Ostia Antica. Rome's aqueduct system provided a stream of non-potable drinking water to flush away waste.

Because of its size and dense population, Rome faced sanitation problems unheard of elsewhere. While garbage collection and disposal were well organized by the standards of the day, they did not meet the city's needs. General collection was restricted to state-sponsored events, and property owners were responsible for cleaning the abutting streets—although the laws were not always enforced. Wealthy Romans used slaves to dispose of their wastes, and some independent scavengers gathered garbage and excreta for a fee and sold the material as fertilizer. When Rome's power waned, the quality of the city's environment deteriorated.

As western Europe deurbanized in the Middle Ages—due in great degree to widespread plagues—people were spared the massive waste problems experienced by densely populated cities. Despite the crudity of medieval dwellings and living conditions, the eventual rise of new cities was accompanied by greater attention to health practices. Cities began paving and cleaning streets at the end of the twelfth century.

The migration of rural peoples to urban places also meant the migration of hogs, geese, ducks, and horses into the cities. In 1131 a law was passed prohibiting swine from running loose in Paris after young King Philip was killed in a riding accident caused by an unattended pig. But animals continued to roam the streets as scavengers. In the great Islamic cities and in China, however, public areas were better maintained than in Europe during the Middle Ages and the Renaissance.

Industrial Age Waste Problems

With the onset of the Industrial Revolution in the 1760s, urban sanitation took a turn for the worse, first in England then on the European continent. The inability to house the growing population migrating to the industrial centers led to serious overcrowding and health problems. As late as 1843, a major section of Manchester had only one toilet for every 212 people.

English cities, however, were the first to establish city services to confront the problems. (Some research suggests that Vienna established a refuse collection system that was one of the earliest on record in the eighteenth century.) While it is easy to exaggerate the range and quality of services provided, the largest industrial cities in England and elsewhere had rudimentary public works and public health agencies by the early nineteenth century.

The rise of public health science was crucial. Cholera epidemics ravaged England in the early nineteenth century, and in the late 1820s many people accepted chronic dysentery and other endemic diseases as normal. The 1842 Poor Law Commission's *Report on the Sanitary Condition of the Labouring Population of Great Britain*, authored by Edwin Chadwick, came to the conclusion that communicable disease was related to filthy environmental conditions. The filth—or miasmatic—theory of disease was the most significant force for promoting environmental sanitation until the twentieth century, when the germ theory identified bacteria as the culprit in spreading communicable diseases.

While Europe was in the throes of its Industrial Revolution, the United States was just emerging as a nation. Many of the European lessons about sanitation, therefore, were not applied immediately. Early America was highly decentralized, and the smaller towns and cities did not face the enormous waste problems of London or Paris. Yet habits of neglect affected these communities too. Casting rubbish and garbage into the streets was done casually and regularly, despite the fact that crude sanitary regulations were common by the late seventeenth century in

major towns. In 1634 Boston officials prohibited residents from throwing fish or garbage near the common landing. In 1657 the burghers of New Amsterdam passed laws against casting waste into streets.

By and large, sanitation in preindustrial America was determined by local circumstances. Some city leaders placed a high priority on city cleanliness, applying the principles of environmental sanitation. Others simply ignored the problem. Individuals or private scavengers usually collected refuse. Boards of health were slow in developing, understaffed, and limited in power. It was not until 1866 that New York City became the first American city to establish a systematic public health code.

The solid waste problem became a serious issue in American cities during the Industrial Revolution. Crowded cities produced mounds of garbage. Coal mines left hills of slag. Pigs or turkeys still roamed the streets and alleys in some towns looking for scraps; horses dumped tons of manure into thoroughfares; and rivers, lakes, and the oceans became sinks for tons of urban discards.

Boston authorities estimated that in 1890 scavenging teams collected approximately 350,000 loads of garbage, ashes, rubbish, and street sweepings. In Chicago 225 street teams gathered approximately 1,500 cubic meters of refuse daily. In Manhattan in 1900, scavengers collected an average of 555 tonnes of garbage daily. Because of seasonal variations in available fruits and vegetables, that amount increased to about 1,000 tonnes daily in July and August. One hundred years later, the United States produces more than 226 million tonnes of municipal solid waste each year, and possibly as much as 350 million tonnes per year. This represents almost 2 kilograms per person per day.

The Worldwide Waste Stream

Unfortunately, the United States is a leader in many categories associated with municipal solid waste generation, although the waste problem is not restricted to the United States. While the composition of solid waste varies considerably throughout Europe, organic

material and paper dominate the waste stream. These two categories account for between 50 and 80 percent of residential waste materials. Glass, plastics, and metals make up as little as 10 percent to as much as 25 percent. In Eastern Europe, organic materials are more plentiful than glass, plastics, and metals. Overall figures suggest substantially less use of packaging material in Europe as a whole, for example, than in the United States.

Affluence is a strong dictator of waste volume and variety. For example, in higher-income economies in Israel, Saudi Arabia, and the United Arab Emirates, abandoned cars, furniture, and packaging are openly discarded. In Asia, paper and plastics waste are generally greatest in Tokyo and Singapore, while very low in Beijing and Shanghai (due in part to recovery and recycling). On the Indian subcontinent, organic and inert matter dominates waste disposal, and per capita per day disposal rarely exceeds 0.8 kilograms. The same is true for African cities, where waste is high in organic material and also rarely exceeds 0.8 kilograms. Waste in Latin America generally is high in organic material, but can average 1 kilogram per day.

While the discards of nineteenth-century America were largely food wastes, wood and coal ash, rubbish, and horse manure, the current waste stream includes a complex mix of hard-to-replace and recyclable materials, as well as a variety of toxic substances to a much greater extent than anywhere else in the world. Of all current discards, paper, plastics, and aluminum have increased the most. Paper makes up about 38 percent of the U.S. waste stream; plastics, 11 percent; metals and glass, 19 percent; and yard waste, 12 percent. Solid waste collection and disposal place great strain on local economies, particularly when revenue streams constrict, government priorities change due to political shifts, and support from other governmental entities are diverted elsewhere. There is an informal dimension to the solid waste economy, however, that rarely finds its way to the balance sheet. In countries with thousands of low-income and middle-income people, solid waste often is a major source of income—collected, sorted, and

Waste Management: Public and Private

The way solid waste is managed—or mismanaged—is crucial to the success of collection and disposal practices. Beginning in the late nineteenth century, a major concern of city government in the United States was to determine responsibility for delivering needed services such as refuse collection and disposal. For many years, the question was whether public or private service was better. Between the 1890s and the 1960s, publicly managed systems dominated. In the early twenty-first century, the United States has a mixed system of service providers in the solid waste field, with the trend toward increased privatization. Whatever the system, local governments in North America in general retain primary responsibility for managing or overseeing solid waste management. In Canada the approach favors more decentralization than in the United States.

The recent interest in “integrated waste management” systems, that is, systems that will use some or all disposal options, requires cooperation between public and private parties. In the United States, the

Environmental Protection Agency’s promotion of integrated waste management also suggests a significant role for the federal government in setting a national agenda for solid waste, as well as having an expanded regulatory function.

Since the 1960s, the U.S. federal government has played a greater role in addressing the waste problem, underscoring its significance as an environmental issue with national repercussions. The 1965 Solid Waste Disposal Act was the first major federal law to recognize solid waste as a national problem. Since that time new laws have been added, shifting attention among issues of recycling, resource recovery, conversion of waste to energy, hazardous wastes, and more traditional concerns over municipal solid wastes.

While the United States seeks to implement an integrated solid waste management system, western Europe leads the world in such an endeavor. Governments in all western European countries are required to design their systems around integrated models with waste prevention at the core. While the public sector has been at the center of these programs for years, private companies increasingly carry out waste management services. Even in Eastern Europe where state-run programs have been the norm, private companies

are making headway. In many countries, legislation to improve solid waste management at the highest levels is insufficient, and private sector initiatives increasingly compete with governments to carry out of waste services.

Especially since the 1960s and 1970s, privatization of solid waste collection and disposal proved to be an alternative to municipal service—a form of outsourcing often seen as a way for cities to get out from under an onerous service obligation. While private collection and disposal always has been part of the service mix throughout the world, a relatively new dimension is the development of solid waste conglomerates often with international reach. In the United States, for example, consolidation accounted for much of the industry's growth in the 1990s with some companies becoming international businesses.

Collection Practices

Collection of solid wastes has been made difficult throughout the world by the growing volumes and kinds of materials discarded, the larger populations to be served, and the greater distances that sanitation workers are required to cover. There is no “best” method of collection. Before 1900, some American cities chose to collect unseparated discards, and others experimented with source separation. Historically, collections were most frequent in the business districts, less frequent in outlying areas or poorer neighborhoods. As more affluent suburbs grew, cities diverted collection teams from inner-city routes to upper- and middle-class neighborhoods.

After World War II, technical advances helped to ease the problems of collection, especially in the United States and Europe, with the introduction of compaction vehicles and transfer stations (used as central drop-off points for collected refuse). But over the years collection remained heavily dependent on hand labor in many parts of the world. No matter the method, collection is difficult because it is costly and does not serve every citizen equally well, especially the poor. Surveys estimate that from 70

to 90 percent of the cost of solid waste service in the United States goes for collection. Equally high or higher collection ratios can be found in other areas such as Africa.

Collection of wastes is an imposing task throughout the world. In some cities, such as Kathmandu, Nepal, there is no formal waste collection service of any kind. In Mexico City, the national government controls collection and disposal arrangements, and does not allow private contractors to operate. Throughout Latin America collection coverage is reasonably good in the large cities such as Buenos Aires, São Paulo, Rio de Janeiro, Caracas, Santiago, and Havana, although it is uncertain whether squatter settlements receive adequate collection service. Privatizing collection operations, which became more popular in the United States in the 1960s, also has caught on in several large cities in Latin America.

Conditions in Europe vary greatly. In western Europe and Scandinavia collection is frequent and highly mechanized; in eastern Europe, where much of the housing is multifamily apartments, quality of service is uneven. Like Europe, industrialized countries of Asia—Australia, New Zealand, Hong Kong, Japan, and Singapore—have waste collection in their cities that is mechanized and capital intensive. In developing countries much of collection is done by hand labor, with the exception of some large cities that maintain motorized collection fleets. In the poorest countries, collection rates may not exceed 50 percent and may not extend to the poor.

Privatization also is gaining a foothold in some countries. Most interestingly in east Asia and the Pacific, women often manage garbage in the household, pay for collection service, separate recyclables, and sell items to private waste collectors. In south and west Asia, for example, labor unrest and civil disturbances have affected municipal service periodically. In much of Africa the municipality, through a combination of motorized vehicles, animal-drawn carts, and human-drawn wheelbarrows and pushcarts, carries out collection. As in many developing regions, transfer stations are uncommon and collection reliability is often low.

Disposal Options: Landfills and Incinerators

Modern sanitary landfills evolved from those originating in Great Britain in the 1920s, and American attempts in the 1930s in New York City, San Francisco, and especially Fresno, California. The sanitary landfill is composed of systematically dug trenches, where layers of solid waste alternate with layers of dirt. The trenches are then covered with a layer of dirt so that odors could not escape and rodents and other vermin could not enter. Newer landfills utilize plastic liners to retard leaching and monitoring devices to detect methane emissions and various other pollutants.

Through the 1950s and 1960s engineers and waste managers believed that the sanitary landfill was the most economical and safest form of disposal. By the 1970s, experts began to doubt that landfills could serve the future needs of cities, not only because of the paucity of land but also because of citizen resistance and increasingly rigid environmental standards. The NIMBY syndrome—Not in My Back Yard—spread across the country as some neighborhoods refused to act as dumping grounds for the whole community. Many times sanitary landfills did not live up to their name, becoming a haven for insects and rodents, threatening groundwater, producing methane gas linked to ozone depletion, and containing various hazardous materials. In some cases, the placing of dumps in minority neighborhoods was and is challenged as a form of environmental racism. In the 1980s, the siting of hazardous or potentially hazardous waste facilities in the neighborhoods of people of color helped to inspire a form of “ecopopulism” in American cities under the rubric of the “environmental justice movement.” At first, such efforts at confronting social and environmental injustice with strong racial and class overtones remained in an American context, but in time similar concerns over intentional placements of unwanted facilities grew beyond “NIMBYism” elsewhere to articulate similar concerns.

By recent estimates, 55 to 70 percent of the waste generated in North America ends up in landfills. But

the total number of sites in the United States particularly declined through the late 1980s and 1990s substantially, from approximately 8,000 in 1988 to 2,300 in 1999. The major reason for the decline, in addition to siting problems, is Subtitle D of the Resource Conservation and Recovery Act (1976), which set and enforced rigorous national standards for municipal solid waste (MSW) landfills in the 1990s. In essence, newer, larger, but fewer landfills could meet the new standards, while smaller and older ones simply stopped operating.

The lack of sites in the United States, especially in the East and parts of the Midwest, forced several states to export their garbage. New York is the top exporter with 5.0 million tonnes per year, followed by New Jersey and Missouri (1.6 million tonnes) and Maryland (1.4 million tonnes). The major importer of waste is Pennsylvania with 9.0 million tons per year followed at some distance by Virginia (3.5 million tonnes) and Michigan (2.8 million tonnes).

There is a clear split between northern and southern/eastern Europe in the use of landfills. In some northern European countries landfill practices parallel current U.S. experience with approximately half of the waste finding its way to landfills. In Greece, Spain, Hungary, and Poland, virtually all collected waste goes into the ground. Many of the landfills in Europe are of the small, uncontrolled municipal type, but efforts are being made to shift toward larger regional types. Unlike the U.S., NIMBYism is unlikely to influence the siting of landfills.

Landfilling has been the cheapest and most typical form of disposal in east Asia and the Pacific. But in countries such as Australia, Japan, and Singapore, costs have risen sharply in recent years. In developing countries, open dumping rather than sanitary landfilling has dominated disposal practices. The same is true in south and west Asia and in much of Africa. Egypt and South Africa tried to upgrade landfills, but this objective has yet to achieve success. Waste pickers—sometimes operating under municipal authority or on their own—work the open dumps to find materials to utilize or sell. Ocean dumping is still common in these regions as well,

The world is too much with us; late and soon, / getting and spending, we lay waste our powers: / Little we see in Nature that is ours. • William Wordsworth (1770–1850)

although the practice is banned or restricted in most places.

The use of landfills—many of them private—in Latin America and the Caribbean is on the rise, especially in large cities. These sites, however, more closely resemble controlled dumps than sanitary landfills. In Mexico, for example, there are nearly one hundred controlled disposal sites, but only about 10 percent (mostly in the north) can be considered sanitary landfills. Waste pickers also are common in Latin America, and while attempts have been made to prevent them from entering the dumps, such efforts normally fail.

Of the available alternatives, incineration has had the strongest following. The first systematic incineration of refuse at the municipal level was tested in Nottingham, England, in 1874. Two years later in Manchester, Alfred Fryer built an improved “destructor,” and subsequently the British led in the technology’s development for several decades. The British were the first to attempt to convert the heat from burning waste into steam to produce electricity. The first American “cremators” were built in 1885.

Two types of combustion facilities—both with roots in the late nineteenth and early twentieth centuries—were developed in the late nineteenth and early twentieth century. The first is a mass burn unit used to reduce the total volume of waste; the second is the waste-to-energy facility, pioneered by the British, meant to produce steam to generate electricity or to be sold directly to customers as a heating source. Waste-to-energy became popular in the United States in the 1970s in the wake of the energy crisis, but it did not gain widespread support, nor did incineration in general.

Despite the fact that incineration drastically reduces the volume of waste, the cost of the technology and chronic problems with air pollution made it a weak competitor in contests with the sanitary landfill. In the 1990s, however, incineration rebounded, especially built on the hope of an improved competitive edge because of rising landfill fees and the promise of cleaner energy production. In 1996, 110

combustors with energy recovery were in operation in the United States with a capacity to burn up to approximately 90,000 tonnes of MSW per day; the number is much lower in Canada. Overall, waste-to-energy incineration handles approximately 10–15 percent of the solid waste stream in North America.

Incineration also has a checkered history internationally. In Africa any kind of burning and waste-to-energy—except medical waste incineration—are little used because of high costs. The same is true in Latin America. In Asia, only cities in the most industrialized countries use modern incinerator technology. Japan leads the way; Tokyo has thirteen incinerators. The increasing lack of landfill space and the dense population has put Japan on the forefront of incineration use and development. In developing countries, many problems have arisen with imported incinerators. Some units do not operate at high enough temperatures to destroy pathogens and the high moisture content in the waste, and they contribute substantial air pollution.

Europe’s commitment to incineration since the early successes in England has been mixed. Northern European countries, particularly Sweden, rely heavily on mass-burn incineration in association with energy generation. In western Europe anywhere from 35 to 80 percent of residential waste is incinerated. The lack of landfill space and energy needs have been powerful forces in promoting the burning of waste, but not without controversy. Emissions of acid gases, heavy metals, dioxin, and mercury have caused serious concern, and have led the European Union to enforce stringent emissions standards for incinerators. Older incinerators that do not generate energy are being phased out.

European countries have been active in producing by-products from incineration residue, using fly ash, for example, in a variety of road products. Europeans also have led the way in developing refuse-derived fuels. The experiences in eastern Europe have been less successful, especially because of the older incineration facilities in use and the inability to upgrade or replace them.

Recycling and Recovery

Only in the last several years has recycling emerged as an alternative disposal strategy to landfilling and incineration, particularly in the United States. Once regarded as a grassroots method of source reduction and a protest against over consumption in a “throw-away society,” recycling arose in the 1980s as a disposal method in its own right. In 1988 about 1,000 communities in the United States had curbside collection service; in 2000 the number exceeded 7,000. The province of Ontario initiated its first curbside program in 1983, and by 1987 at least forty-one communities had such programs in Canada. The EPA estimated that recycling and composting diverted 52 million tonnes of material away from landfills and incinerators in the United States in 1996 (up from 31 million tonnes in 1990), with the most typical recyclables being aluminum cans, batteries, paper and paperboard, and yard trimmings.

A major goal of many communities and the United States in general is to increase the recycling rate, which stood at 10 percent in the late 1980s. The EPA's 1988 draft report on solid waste called for a national recycling goal of 25 percent by 1992. In the late 1990s, the EPA raised the goal to at least 35 percent of MSW by 2005, and called for reducing the generation of solid waste to about 2 kilograms per capita per day. The actual rate of recycling in the late 1990s was about 20 to 25 percent in North America.

The U.S. experience with recycling, while vastly changed from years past, falls short of recycling and recovery efforts in other parts of the industrialized world. Germany and Denmark, in particular, have aggressive recycling policies. Denmark, for example, recycles about 65 percent of its waste. One of the most unique aspects of recovery of materials in western Europe is the pervasive idea of “producer responsibility” for proper disposal of packaging and other products. Recycling and recovery in southern and eastern Europe and in other parts of the world is more uneven. Throughout Latin America and the Caribbean, materials recovery is extensive with recycling

programs in all large cities and most moderate-sized communities. In smaller towns and rural areas, where much of the waste is organic, composting is the only form of recovery in use. Centralized composting has not been successful in Latin America as a rule, however. By contrast, backyard composting is more widespread in Australia, Japan, and New Zealand. In Asia a large portion of household organic waste is fed to animals. The large composting plants that were so prevalent throughout developing countries in Asia—including those pioneered in India—are out of use and not working at full capacity.

In east Asia and the Pacific, formal and informal source separation and recycling programs are practiced. The highest degree of waste reduction takes place in the thriving urban areas of Australia, New Zealand, Japan, Korea, and Hong Kong. There also are waste recovery programs and recycling efforts sponsored by cities and national ministries in the People's Republic of China and Vietnam.

Informal waste picking is widespread throughout the world, particularly in developing countries. In several locations, such as in south and west Asia and Africa, there are informal networks of pickers, buyers, traders, and recyclers in place of formal public systems or private companies. Materials recovery takes on a different form in the developing world as opposed to highly industrialized regions. For the former, materials recovery becomes a necessity in areas of poorly paid or unemployed people and in areas where resources are scarce. In industrialized areas, materials recovery is an attempt to lessen the wastefulness of growing economies and reduce environmental costs.

The waste problem is a part of life—ancient and modern. Strides have been made throughout the world to confront the complex problems of waste generation, collection, disposal, and materials recovery. Finding a way to manage solid waste in order to preserve resources and minimize pollution is a constant challenge.

Water

Water is essential for life. In addition to consumption, water is used for travel, power generation, hygiene, recreation, agriculture, industry, ritual, and more. While water covers about three-quarters of the Earth's surface, less than 2 percent of it is fit to drink. Access to water continues to play a crucial role in the location and movement of peoples and communities.

Water covers nearly 75 percent of the Earth's surface and is an integral component of every living being. Fresh water is essential for human survival; while a person can live for weeks without food, one can only survive a few days without water. Throughout history, the location of available water has played an important role in human development and influenced settlement patterns and farming, social customs, religion, transportation, and power generation.

Settlement

The availability of fresh water for human and animal consumption and crop irrigation has influenced human settlement for many millennia. Even though water covers much of the Earth's surface, less than 2 percent of it is potable. While many different peoples have learned to adapt to harsh or unforgiving environments, water from natural springs, rivers, or rainfall is a necessity for survival. During the early history of humans, the availability of water played an important factor in their survival strategy.

During the Neolithic Age, hunters and gatherers stopped migrating, built permanent dwellings, and became farmers and herdsman. When they chose a

site to build their towns, it was usually near an available water source, such as a river or lake. One of the oldest towns, Catalhuyuk in Turkey, serves as a model for these early Neolithic sites. Catalhuyuk, which was established around 7500 BCE, was located very close to several standing bodies of water, and archaeologists believe water was available near the town all year round. Its farmlands appear to be several kilometers farther away from the town than the water supply, underscoring the importance of easy access to water. This model can also be seen at other Neolithic sites, like Choirokoitia in Cyprus, which dates to 7000 BCE.

As the population steadily increased during the period from the Neolithic Age to the Iron Age, settlements began appearing in areas where water was not readily available in large quantities or was not available throughout the year. To survive in these regions, humans had to find ways to adapt their survival strategy to provide enough water to sustain life. One of the most widely practiced solutions was to collect water during times when it was plentiful for use at a later time when it was scarce. Different cultures found various ways to accomplish this. In Greece, Italy, and Mesopotamia, the farmers relied on winter rains to provide enough rainfall to allow summer "drought farming." The winter rains provided enough water that farmers could successfully grow crops with minor modifications to their schedule. They would plant their crops in the early spring while the soil was still well watered from the winter rains and harvest them in the early summer before all the moisture was lost from the soil due to warm and arid summer weather patterns. Inhabitants in these regions relied on natural springs and rainwater collected in large cisterns

People socialize while drawing water from the community well in a village in India. Photo by Klaus Klostermaier.

to ensure an adequate drinking-water supply for the summer and fall months.

In Arabia, the Nabataeans used a system of rock-cut channels and pipes to collect rainwater for storage in underground cisterns, which were lined with waterproof cement. In Egypt, the Nile provided water for irrigating fields, and the annual flooding of the river deposited new soil on the fields and prevented soil depletion. In the Hellenistic Age, an elaborate system of irrigation ditches was implemented to expand the amount of cultivable land. This irrigation system continued to develop and expand through the Roman, Byzantine, and Islamic periods.

In ancient Persia farmers developed the underground irrigation systems known as *qanats* as early as the first millennium BCE as a method for delivering water to their crops. A *qanat* was an underground enclosed canal that collected groundwater in the mountains and carried it to fields in low-lying areas using gravity. Along the length of the *qanat*, shafts would be placed at regular intervals to allow access to the water channel for cleaning and repair. *Qanats* often involved extensive engineering, were up to 40 kilometers in length, and were buried up to 100 meters below the surface. This system of irrigation was adopted by the Arabs and Byzantines. There are more than forty thousand known *qanats* in Iran with many still in use today.

Collecting and storing water for long periods often created a new problem when the water became impure or collected sediment. Many ancient civilizations developed techniques for purifying stored water in an attempt to produce better drinking water. Ancient Sanskrit writings dating to 2000 BCE describe different methods for purifying water by boiling or using sand or charcoal for filtering out impurities. Egyptian tomb paintings depict a device for filtering water that allowed sediment and other impurities to settle to the bottom of a collection device, allowing the clear water to be collected from the top.

While farmers needed to live near water sources for crop irrigation, as cities grew larger they also needed water for the sustenance of their citizens and for maintaining sanitary conditions in the city. Cities depended upon engineers to design systems for delivering water from its source across many miles to its final destinations in the city. Both Rome and Constantinople developed impressive aqueduct systems for bringing water to numerous baths, fountains, and private houses. During the third century CE, Rome had nine functioning aqueducts, which provided over 3 million gallons of water each day to the city. The longest of these aqueducts was more than 95 kilometers in length. The beginning of the aqueducts was simply a channel cut into the earth with a slight downward gradient that used gravity to move the water toward Rome. As the aqueduct left

the hills and approached the city the water channel was carried on raised arches, often more than thirty meters above ground. These channels were 1 meter wide and 1.8 meters high so that workers could enter the channel for cleaning. Three of the aqueducts are still functioning today.

Social Aspects

Water has also played an important role in social customs. Bathing was an important ritual in ancient Greece and Rome. Public baths became common in Greece starting in the fifth century BCE. Adopted by the Romans, bathing became an important social aspect of everyday Roman life by the first century CE, and an important center for social interaction between citizens. Every town would have at least one public bathing structure, and houses of wealthier citizens would have private baths. These bathing complexes would have rooms with differing water temperatures: cold water, tepid, and hot water baths. Larger complexes even had large swimming pools. As the Roman Empire expanded in the second and third centuries CE, these complexes became more and more elaborate with vaulted ceilings, glass windows, exotic artwork, and intricate plumbing systems. The baths built by the Roman emperor Caracalla (Marcus Aurelius Antoninus) in 217 CE could accommodate over 1,600 bathers at the same time. These

bathing complexes were an important tool for the spread of Roman culture and ideas throughout the empire. Bathing is still an important aspect of some modern cultures like Japan and Finland.

Religion

In ancient Greece and Rome, water was an important element in religious rites. Natural springs were considered powerful locations and often became cult worship sites. Along with fire, water was used as a purification element in birth, marriage, death, and sacrificial ceremonies. The idea of water as a tool to purify or remove evil is reinforced by the numerous flood stories from around the globe that recount how god(s) cleansed the Earth of evildoers and made a fresh start with a chosen one, such as Noah in the Old Testament, Deucalion in Greek mythology, Utnapishtim in the *Epic of Gilgamesh*, or the East African story of Tumbainot.

In Greek philosophy and cosmology, water was considered to be one of the four basic elements of the universe in addition to fire, air, and earth. The pre-Socratic philosopher Thales of Miletus, writing in the late fifth century BCE, believed the principal element of all things was water, and everything else in the universe was a creation of water.

In Zoroastrianism, cultivation of the soil was praised and any action that promoted cultivation

Paolo Uccello, *Flood and Waters Subsiding* (1447–1448). The fresco, in Santa Maria Novella in Florence, illustrates the Old Testament story of Noah and the ark.

Humans throughout history traveled waterways large and small as they explored and settled the Earth. In this early-twentieth-century photo, a traveler and his guide raft down the Amazon River in South America.

vation was encouraged. This motivated the Sasanian kings who ruled Persia (modern-day Iran) from the third to seventh centuries CE to build dams and extensive irrigation systems.

In early Christianity, water was seen as a symbol of purification and life. In Byzantine church liturgy, the blessing of the water was an important ritual and was believed by the church leaders to commemorate Jesus Christ's baptism by John the Baptist. Water remains an important purifying element in modern religions. In many modern Christian sects, baptism (either by sprinkling or immersion) in water to wash away earthly sin is an initiation rite of the faith. In Islam, believers wash their hands, arms, feet, and head to cleanse themselves before praying. Judaism also uses water to purify believers and to cleanse them after coming into contact with unclean items, such as a dead body.

Transportation and Empires

With so much of the Earth covered by water, boats have been a necessity for exploration and travel.

Travel via water transport, until modern times, has been faster and less expensive than travel overland. The edict issued by the Roman emperor Diocletian in 301 BCE, which was designed to control maximum prices, provides historians with enough information to formulate standard costs of transportation during this period. The document shows transporting goods overland cost between 30 and 50 percent more than sending them by boat. Travel time was also significantly less, provided the weather was favorable.

As commerce increased, merchants and nations tried to find ways to increase the speed and capacity of ships. This led to the development of the carrack and caravel, ship types that could carry larger cargoes and sail faster and required fewer sailors. Another method of shortening the time of sea travel was the creation of canals that linked major bodies of water, eliminating circumnavigation. This led to the building of the Grand Canal (486 BCE), Erie Canal (1825 CE), Suez Canal (1869), Corinthian Canal (1893), Panama Canal (1914), and Rhine-Danube Canal (1992).

Cities or nations whose citizens became skilled at seamanship or building boats were able to capitalize on this and create large empires, commercially or militarily. By the eighth century BCE, the Phoenicians were able to create a trading network that included the entire Mediterranean Sea and as a result spread Phoenician culture to many different regions. The success of the Phoenicians was repeated on a smaller scale by the Venetians in the Mediterranean and the Hanseatic League in the Baltic Sea in the thirteenth and fourteenth centuries CE.

Cultures that relied on overseas transportation for their commercial goods often developed a strong navy to protect their commercial interests. In the fifth century BCE, the city-state of Athens was able to use its strong maritime presence in the Aegean to create the Athenian Empire. In the fifteenth century CE, England was able to use the development of its mercantilist policies to create both a strong merchant marine and a strong navy. England was able to use its naval power to further its political

policies abroad and build up an empire that spanned the globe.

Water Power

Water has also been used to drive machines and create energy. One of the earliest inventions was a waterwheel that used falling or flowing water to drive a shaft that would then turn the mill. Ancient Greeks and Romans were the first to use waterwheels to power mills for grinding grain into flour, and this practice continued through the medieval period.

With the development of a successful steam engine in the early eighteenth century, the use of waterwheels declined. In the United States during the eighteenth and nineteenth centuries, waterwheels were used to supply power to sawmills, grain mills, and textile factories. In 1882 the first power plant that derived its energy from water was constructed in Wisconsin. By the early 1940s hydroelectric power provided nearly 40 percent of U.S. energy consumption. Today, Canada, New Zealand, Norway, Switzerland, and Sweden depend heavily upon hydroelectric power.

Water in the Twenty-First Century

Since the mid-1980s many nations have come to realize that water is not a limitless commodity and that steps have to be taken in order to protect this valuable resource for future generations. In the twenty-first century several key water issues have emerged. First, as the world's population increases, more countries are unable to meet the increased demand for drinking water. Second, industrialization leads to increased pollution, which further decreases the amount of available drinking water. Third, continued urbanization and deforestation have led to increased flooding and soil erosion. Fourth, as countries look to augment their existing water supply, conflicts over water sharing, particularly of international rivers, have increased. Increased public awareness about these important environmental issues has resulted in the formation of international agencies

that are attempting to solve these problems and implement water resource management plans.

While access to clean water is an increasing concern, it is thought that there is currently enough water for everyone. The problem is the inefficient and ineffective management of water resources. As such, every year millions of people die from waterborne diseases because of their lack of essential access to a clean water supply. Some of the possible remedies to water shortages and inequities include recycling and redistribution.

Water Energy

Mechanical (kinetic) energy of flowing or falling water was traditionally converted to rotary motion by a variety of waterwheels, and, starting in the 1880s, by water turbines that have been used to turn generators. Unlike fossil fuels, this form of electricity generation does not produce air pollution directly, but its other environmental impacts have become a matter of considerable controversy.

It is not known by how many generations or centuries the origins of waterwheels predate the first reference to their existence by Antipater of Thessalonica, who wrote during the first century BCE about their use in grain milling. A millennium later such simple devices were common in parts of Europe: in 1086 the *Domesday Book* listed 5,624 mills in southern and eastern England, one for every 350 people. The usual arrangement was to channel flowing water through a sloping wooden trough onto wooden paddles, often fitted to a sturdy shaft that was directly attached to a millstone above. Vertical waterwheels, first mentioned by Vitruvius in 27 BCE, were much more efficient. All of them turned the millstones by right-angle gears, but they were propelled in three distinct ways.

Wheels and Turbines

Undershot wheels were driven by kinetic energy of moving water. As doubling the speed boosts the capacity eightfold, they were preferably located on swift-flowing streams. The best designs could eventually convert 35–45 percent of water's kinetic energy

into useful rotary motion. Breast wheels were powered by a combination of flowing and falling water and operated with heads between 2 and 5 meters. Overshot wheels were driven primarily by the weight of descending water and hence could be located on streams with placid water flows. With heads over 3 meters their conversion efficiencies were commonly in excess of 60 percent with peaks of up to 85 percent. Wheels, as well as shafts and gears, were almost completely wooden until the beginning of the eighteenth century; hubs and shafts were the first iron parts and the first all-iron wheel was built early in the nineteenth century.

Besides the wheels fixed in streams there were also floating wheels on barges and tidal mills and common uses of waterwheels eventually expanded far beyond grain milling to power machines ranging from wood saws and oil presses to furnace bellows and forge hammers, and to mechanize manufacturing processes ranging from wire pulling to tile glazing. Even as their uses widened, capacities of waterwheels remained limited, averaging less than 4 kilowatts in early eighteenth-century Europe. Post-1750 innovations led to a rapid increase of individual capacities as arrays of waterwheels, sometimes rating in excess of 1 megawatt (one megawatt equals one thousand kilowatts), became the leading prime movers of expanded mass manufacturing in Europe and North America. In 1832, Benoit Fourneyron's invention of the reaction turbine ushered in the era of much more powerful water-driven machines. James B. Francis designed an inward-flow turbine in 1847, Lester A. Pelton patented his jet-driven turbine in 1889, and Viktor Kaplan introduced his axial flow turbines in 1920.

Energy can be generated from hydroelectric dams. Here power lines carry electricity generated from a river.

Hydroelectricity

The first water turbines were used merely to replace waterwheels as the prime movers in many industries, but by the late 1880s the machine began to be coupled with generators to produce electricity. The first American hydroelectric plant was built in 1882 in Wisconsin. More than century later, water turns turbines that supply almost 20 percent of the world's electricity. In dozens of tropical countries, water power is the dominant means of electricity production.

Most of the world's hydro energy remains to be tapped. Worldwide total of economically feasible hydro generation is over 8 petawatt-hours (PWh, that is 10¹⁵—one quadrillion—watt-hours) or roughly three times the currently exploited total. Europe has the highest share of exploited capacity (more than 45 percent), Africa the lowest (below 4 percent). The greatest boom in construction of large dams took place during the 1960s and 1970s, with about five thousand new structures built per decade.

Advantages and Drawbacks

The air pollution advantage of hydropower is the most obvious one: if coal-fired power plants were to generate electricity that is currently produced worldwide

by running water, the global emissions of carbon dioxide and sulfur dioxide would be, respectively, 15 percent and 35 percent higher. Hydrogeneration also has low operating costs, and its spinning reserve (zero load synchronized to the system) in particular is an excellent way to cover peak loads created by sudden increases in demand. Moreover, many reservoirs built primarily for hydrogeneration have multiple uses—serving as sources of irrigation and drinking water, as protection against flooding, and as resources for aquaculture and recreation. But during the closing years of the twentieth century, large dams were widely seen as economically dubious, socially disruptive, and environmentally harmful.

Displacement of a large number of usually poor people has been the most contentious matter. Construction of large dams dislocated at least 40 million people during the twentieth century (some estimates go as high as 80 million), and during the early 1990s, when the work began on three hundred new large dams began every year, the annual total reached 4 million people. China and India, the two countries that have built nearly 60 percent of the world's large dams, had to relocate most people: more than 10 million in China and at least 16 million in India. Large hydro projects also have a multitude of undesirable environmental impacts, and recent studies of these

A hydroelectric dam on the Connecticut River between Vermont and New Hampshire, seen through the mist of the rushing water.

previously ignored changes have helped to weaken the case for hydrogeneration as a clean source of renewable energy and a highly acceptable substitute for fossil fuels.

Perhaps the most surprising finding is that large reservoirs in warm climates are significant sources of greenhouse gases emitted by decaying vegetation. Water storage behind large dams has increased the average age of river runoff and lowered the temperature of downstream flows. Several of the world's largest rivers have reservoir-induced aging of runoff exceeding six months or even one year (Colorado, Rio Grande del Norte, Nile, Volta). Many tropical reservoirs create excellent breeding sites for malaria mosquitoes and for the schistosomiasis-carrying snails, and most dams present insurmountable obstacles to the movement of migratory fish. Multiple dams have caused river channel fragmentation that now affects more than three-quarters of the world's largest streams.

Other environmental impacts caused by large dams now include massive reduction of aquatic biodiversity both upstream and downstream, increased evaporative losses from large reservoirs in arid climates, invasion of tropical reservoirs by aquatic weeds, reduced dissolved oxygen and hydrogen sulfide toxicity in reservoir waters, and excessive silting. The last problem is particularly noticeable in tropical and monsoonal climates. China's Huang (Yellow) River, flowing through the world's most erodible area, and India's

Himalayan rivers carry enormous silt loads. Silt deposition in reservoirs has effects far downstream as it cuts the global sediment flow in rivers by more than 25 percent, and reduces the amount of material, organic matter, and nutrients available for alluvial plains and coastal wetlands downstream, and hence increases coastal erosion.

The ultimate life span of large dams remains unknown. Many have already served well past their designed economic life of fifty years but silting and structural degradation will shorten the useful life of many others. As a significant share of the Western public sentiment has turned against new hydro projects, some governments took action. Sweden has banned further hydrostations on most of its rivers, and Norway has postponed all construction plans. Since 1998, the decommissioning rate for large U.S. dams has overtaken the construction rate. Major hydro projects of the twenty-first century will thus be built only in Asia, Latin America, and Africa.

Water Management

Water has many essential uses, including in agriculture, industry, recreation, and domestic consumption, most of which require fresh water (as opposed to saltwater). Only 3 percent of Earth's water supply is fresh, and most of that is frozen. While fresh water is a renewable resource, supply is limited while demand is increasing. This requires careful management of existing water resources.

Land-based life on Earth revolves around sweet (nonsalty) water. Domesticated plants require a regular and sufficient supply of sweet water. People must manage this water resource; they also must manage the supply of sweet water for humans, for domesticated animals, and for manufacturing.

Most of the surface of our planet is water, but most of it is too salty for use by organisms living on land. But the hydrological cycle (the sequence of conditions by which water passes from vapor in the atmosphere through precipitation onto land or water surfaces and back into the atmosphere) provides a continuous supply of sweet water in the form of rain and snow. After precipitation hits the ground it either runs off on the surface, as rivers and other streams, or soaks into the soil. From the point of view of a farmer cultivating fields in a fixed place, the water environment is sweet, with water running on the surface, water in the top layer of the soil (soil water), and water deeper underground (groundwater).

As is true for most life processes, an ideal amount of water exists for the farmer. The environmental supply of water is variable, however, fluctuating from place to place and from time to time on daily, monthly, and

yearly schedules. Combining the need for an ideal amount of water with the unending fluctuation yields three kinds of conditions: about right, too much, and too little. "About right" rarely occurs.

Water has several physical characteristics that are relevant for managing a farm. First, water is liquid and flows easily. Thus all water responds to gravity and naturally flows downhill. It always takes the shortest possible route. Water is easy to move if a downhill path can be found. But because water is a liquid, a sealed container must be used if a person wants to lift it. Second, water is heavy. Lifting it requires not only a sealed container but also considerable energy. Third, water is an excellent solvent. One of the major functions of water in the life of the green plant is to dissolve nutrients (from the soil) and transport them into the plant, but water can also dissolve poisons (including salts). Fourth, water can carry many solid particles in suspension. Erosion of the landscape by running water transports such solid particles downstream.

The farmer wants sweet water for plants in the right amounts, at the right times, moving at the right speeds, and containing the right components (dissolved, suspended). Irrigation is the technology that increases the water supply to plants, and drainage is the technology that reduces the water supply to plants.

The major energy sources for moving water are gravity, human muscle, animal muscle, wind, and heat engines (mechanisms, such as internal combustion engines, that convert heat energy into mechanical or electrical energy). For irrigation we supply water at a high point, and for drainage we remove it at a low point.

The dam at Simatai in March 2004. This Great Wall tourist location to the far north of Beijing is an example of the Chinese commitment to dam building.

Irrigation

The elements of a canal irrigation system are an intake, where ditches tap into a water source; a main canal (sometimes many kilometers long); and a series of branch canals that deliver water to the farmer's fields. Movable gates may control water flow into the branch canals, or the system may be designed so that water flows in every channel simultaneously.

The ditches move the water from the source to the fields. The technology for digging these ditches is simple and has been invented virtually everywhere. People use digging sticks, shovels made of wood, and hoes made of stone to loosen the dirt. Such tools are old and widespread. People use baskets to move the loosened dirt. Because water responds so quickly to gravity, people can easily test whether a ditch has the right slope and change the slope if they have made errors.

Most irrigation systems are what we call “run of the river,” meaning that the water available to them is what is in the river (the source) at the time. The construction problems are obvious (water must flow downhill, dirt must be moved), and the solutions have been invented many times. A significant problem with irrigation systems is variation in environmental moisture. For example, a drought can reduce a river's water supply to a trickle, posing a threat to crops.

One solution to such variation is to store water in a reservoir; however, water storage was quite rare in early world history. The city of Jawa in the Jordanian desert had a storage dam by about 4000 BCE. Tank irrigation systems that stored water behind a small dam were widespread in southern and southeastern Asia by the first millennium BCE. Roman engineers built many small storage dams of masonry, but these dams may have been meant for domestic use rather than for irrigation. An early dam in the Americas was the Purron Dam in Mexico, dated to about 800 BCE. That dam was made of earth and at its maximum was 19 meters tall. The dam was in operation for approximately one thousand years and could store more than 3 million cubic meters of water. Purron was one of only two storage dams known to have existed in the highland area of Mexico. Since the late nineteenth century people have built many massive storage dams in most parts of the world. Machinery and modern materials—and a plentiful supply of money—have been central to these efforts.

Early irrigation systems built with simple tools were probably widely distributed. Their existence is difficult to document because all subsequent irrigation systems in the same place used the same routes for the ditches. Thus researchers have difficulty finding and dating the earliest occurrence. Scholars, however, think they have evidence of irrigation early in

all of the world's civilizations. Irrigation may have existed during Neolithic times as well. The tools to build such systems were already available, as was the social organization. Only so many effective designs of an irrigation system exist, and they have existed around the world during all time periods.

Drainage

Drainage systems are the reverse of irrigation systems. Irrigation systems move large amounts of water to the top of the fields, and then break it down into smaller and smaller packages for distribution to fields. Drainage systems collect small amounts of water at many places high up in the system, combine these small amounts into larger and larger channels, and collect the total at the bottom of the field system. The problem then is where to put the drainage water; if it accumulates it can flood the lower fields. The drainage water so collected is eventually put into a large body of water (a river, the ocean), and often people can use gravity to put it there. Gravity works well as an energy source, and ditches again are used to channel the water. Another technology for draining water is tile pipes. The pipes, with holes in them, are installed in ditches in the fields and then covered up. The lower end of the pipes must drain into something, usually a riverbed. Tile pipes are effective and virtually invisible to all but the most discerning eye.

Another way to drain water is to dig dirt out of a swamp and pile it up so that the top is above the water level, producing what are often called "raised fields." These fields can vary in size from a few square meters at the edge of a swamp to thousands of hectares. Among the earliest water management systems using raised fields were in highland New Guinea, dated to about 5000 BCE.

Lifting Water

Because of water's weight and liquid nature, people had difficulty lifting water for many millennia. People used human muscle to lift small amounts of water in pots to water individual plants in the

Valley of Oaxaca, Mexico, about 2000 BCE. In Egypt they could lift larger amounts with the *shadoof* (a beam on top of a pole with a counterweight at one end and a container for the water on the other end). Human muscle powered the *shadoof*. Wells (vertical shafts from the surface down to the water table) have been dug for a long time, but extracting large amounts of water has been difficult. People have used large domesticated animals to power the raising of larger amounts of water, but the output has not been substantial.

In the dry mountain belt from Turkey to western China, horizontal wells (called *qanats* or *foggara*) were widespread. A shaft was dug from the point of use (often an oasis) into a mountain, gently sloping upward, until the shaft met with water-bearing earth. Then a vertical shaft was dug down to the horizontal shaft to remove dirt and to gain access for repairs. Horizontal wells could exceed 60 kilometers in length. They could provide water for centuries if properly maintained.

The first major innovation that increased people's ability to lift water was the windmill, which became prominent in northwestern Europe during the thirteenth century. The Dutch reclaimed low land from the sea by building protective dikes, and they then drained the water out of the low land behind the dikes. They ganged together large windmills to lift the water out of the low land and dump it into the sea or a river outside the dikes. The height to which water could be raised was limited, however, and the windmills could operate only when the wind was the right speed.

With the advent of the heat engine during the Industrial Revolution the limits on lifting water were eliminated. One of the first tasks given to steam engines was to drive pumps that drained water from flooded coal mines. Later uses included pumping drainage water out of a basin and lifting water for irrigation. Water could be lifted from a surface source (such as a river or lake) or from a deep well. Today a great deal of irrigation water is acquired from deep underground; this could not be done without the heat engine to drive a pump.

With the introduction of the internal combustion engine, small pump and driver (an engine that powers the pump) sets became feasible, even to the point that farmers could own such sets and move them around the farm to where they were needed. Although such sets save labor, they are expensive in terms of energy.

A modern innovation in irrigation technology is the pressurized system. Two major forms are used: sprinkler systems and drip systems. In sprinkler systems a pump and driver pressurize water, which is then moved through a series of pipes that is above the level of the plants that are to be irrigated. These pipes have multiple nozzles, and the water distribution mimics light rain. There are two major advantages of this system: (1) water use is much more efficient (more than 90 percent of the water reaches the crop root zone; by contrast, ditches have efficiency as low as 50 percent), and (2) no need exists to sculpt the surface of the soil, thus saving labor and energy. A small computer can operate a number of these sprinkler systems, saving even more labor. These systems also can deliver chemicals (fertilizers, pesticides) in the water. The major disadvantage is that the technology is energy intensive. Sprinkler systems are used throughout much of the world; people flying at 10,000 meters in an airplane can see the green circles made by a rotary sprinkler system.

The other form of pressurized system is drip irrigation. Developed mainly in Israel (where the need to conserve water is great), drip irrigation uses long hoses with holes in them that are buried in the root zone. Water is forced through the hoses and exits the hoses through the holes. Fertilizer and pesticides can be added to the water, thus delivering them directly to the root zone. These systems are even more efficient than sprinkler systems, approaching zero-percent water loss, and they save on the labor to apply fertilizer and pesticide. A major disadvantage is the cost in energy to run the system. Another disadvantage is that the holes in the pipes can clog, which requires that the hoses be exposed; this means excavating them, with possible damage to the crops.

Water Management in History

People have used irrigation systems and drainage systems to manage water for thousands of years and have built and operated such systems without writing and without scientific laboratories. The relationship between water stress (too much, too little) and the health of a green plant is obvious to most observers. People can use simple tools, easily made, to loosen and move dirt to dig ditches. A modern scientific understanding of water, green plants, soil, solutions, the hydrological cycle, and photosynthesis began during the nineteenth century and is still generating knowledge. People needed instruments (microscope, thermometer, balance) and the disciplines of physics, chemistry, anatomy, and physiology to achieve the scientific knowledge that we now have.

The impact of irrigation and drainage on world history has been great. Irrigation and drainage permit people to grow crops where otherwise it would be difficult or impossible. The growing of crops in turn permits a larger, denser population. These technologies have been important in the birth of cities and have played a role in economic surplus, full-time division of labor, metal tools, astronomy, and eventually other sciences. But people also built and operated water management systems for millennia in areas that did not necessarily establish cities and acquire writing (such as New Guinea in the Malay Archipelago and the Hohokam people in Arizona).

Irrigation and drainage change the water balance of the landscape, and along with agriculture they change the plants and animals there. In order to safely grow domesticated plants and animals, people often have wanted to eliminate native plants and especially animals that are dangerous. Entire landscapes have been changed in ways that we could call domestication. At the same time, however, we have provided habitats for small, dangerous life forms that generate and carry diseases, such as malaria. The blessings are mixed.

The simple tools and knowledge needed to build and operate irrigation systems and drainage systems exist everywhere, and traditionally there was little variation in the forms of such systems. With the

Multiple hand-built terraces and rice paddies in the Nepal Middle Mountains east of Kathmandu are a remarkable feat of engineering; the irrigation system demonstrates how indigenous peoples prove to be outstanding soil conservationists. Photo by Jack D. Ives.

Industrial Revolution, however, European colonial powers built large storage dams during the nineteenth and twentieth centuries. Storage dams were not new, but the scale of them was. The practice of lifting water with heat engines diffused widely. Today people everywhere use heat engines linked to pumps, replacing traditional systems. Significantly, the technology is also manufactured just about everywhere.

The Future

The future of water management is unclear. World population is growing, and such growth will increase the demands for food and space for buildings. A substantial portion of the world's food is now grown with irrigation, and this portion will only increase in the near future. An easy way to gain space to build is to drain wetlands. With industrial technology and (cheap) energy, we have the technical capacity to build and operate large water management systems.

But the best places for storage dams have already been taken, and finding new sources of water will be

increasingly difficult. The draining of wetlands has significant environmental consequences. Industrial populations are voracious users of water (for toilets, manufacturing, mining, irrigation, recreation, etc.), and thus pressure to limit the amount of water that farmers can use is growing. Multiple uses of sweet water (for navigation, recreation, biological diversity) grow in number and in intensity. No clear way exists to solve the water problems that occur in nearly every nation. One technical solution is to increase the efficiency of our water use, and science and technology will be crucial in that solution. The problems are not just technical ones—the beliefs and expectations of the consumers of water are also relevant and far less understood than are the properties of dirt, plants, and water.

Western civilization is a historical concept with a recent origin and uncertain future. The term became a secular equivalent in the United States to “Latin Christendom,” but it never took firm hold in Europe, where national differences loomed too large. As globalization advances, the separateness of local civilizations blurs; historians, reflecting their times, have begun to emphasize transcivilizational connections while questioning the coherence of Western or any other regional civilization.

The word *civilization* entered English from the French in the late eighteenth century, and initially meant polite behavior, just as it did in French. It referred to manners that permitted a person to find his or her proper place in polite society; that meant using words and gestures to defer to superiors, snub inferiors, and climb as high as one could by peaceable means. Bearing, conversation, and clothing all mattered; so did wealth, and familiarity with art, literature, and music also helped to improve a person’s claim to be civilized. It differed from older courtly ideals inasmuch as no monarch set the tone or conferred formal rank. Civilization instead was an urban upper-class phenomenon whose exact definition evolved in accordance with prevailing opinions among those who participated in polite society.

To begin with, such behavior was conceived as potentially universal. To be sure, civilization was most perfectly expressed in Parisian drawing rooms, theaters, and other public places, with London a close rival. But privileged urban circles in Germany, Russia, and other European countries did their best to imitate French manners, often going so far as to read

and speak French and import the latest fashions from Paris. This sort of “civilization,” however contagious it proved to be, was limited to narrow elites, even within France itself. Even before the eighteenth century ended, a reaction set in among Germans, some of whom preferred to believe that their language and culture embodied a unique spirit that was incompatible with French “civilized” ways of thinking and acting.

Camille Léopold Cabaillet-Lasalle, *Le Salon de 1874*. Oil on canvas. Parisian drawing rooms, theaters, and salons embodied the original late-eighteenth-century meaning of the word “civilization”: polite behavior.

A World War I propaganda poster by Frederick Strothmann depicts a German soldier as a “Hun” with a blood dripping from his bayonet and fingers. Library of Congress.

Early in the eighteenth century, patriotic Germans persuaded themselves that German *Kultur* was intrinsically superior to French *civilization*, and Russian Slavophiles soon argued for the superiority of the Slavic soul over more westerly versions of *Kultur* and *civilization*. Meanwhile in France and England, easy and rapid imperial expansion in Africa and Asia seemed evidence of their superiority to other peoples; and the term *civilization* was broadened to describe the achievements of British, French, and European society as a whole. French and British empires were the most extensive, and both countries were situated in western Europe; but no one made much of that geographical detail. (The words *West/Western* as cultural entities are typically capitalized, while *west/western* as geographic distinctions are commonly lowercase.) Before World War I, by and large, *civilization* was

conceived as unitary, centered in Europe, and destined to illuminate and eventually improve the lives of other peoples in colonial (and ex-colonial lands like the United States) as they learned the skills and style of civilized behavior from contacts with civilized Europeans.

This intellectual landscape altered abruptly during World War I. In particular, the concept of Western civilization came to the fore in the English-speaking world when defense of “Western civilization” against the attacking Germans became a theme of British propaganda. In an incautious moment, Kaiser Wilhelm actually told his troops to mimic the fury of the Huns; by calling German soldiers “Huns,” British propagandists were able to confuse the obvious fact that Germans shared Western European civilization and made them out to be barbarians from the East. To be sure, concepts of West–East polarity had antecedents going all the way back to Herodotus who had contrasted free Greeks on the western side of the Aegean Sea with enslaved Persians coming from the east. And British war propaganda rejuvenated that motif by celebrating British and French “liberty” as against Germany’s imperial, aristocratic and wickedly aggressive government. When the United States entered the war in 1917, President Woodrow Wilson chimed in by claiming his government’s purpose was to make the world safe for democracy.

After 1918, these wartime follies were soon abandoned in Britain and France, but not without some sense of shame. Throughout Europe, separate nationalistic histories, elaborated during the nineteenth century, continued to dominate classrooms in schools and universities. Accordingly, differences among the countries and peoples of Europe seemed more significant than “Western” or any other sort of shared civilization. Instead each nation treasured its own grievances against neighbors and cherished its own claims to greatness. Conviction of European superiority to Asians and Africans persisted, but that was based more directly on skin color than on such an intangible as Western civilization.

*Our speculation has burst through the ramparts of heaven,
not content to know merely what is shown to it.* • Seneca (4 BCE–65 CE)

Western “Civ” Enters College

In the United States, however, the concept of Western civilization had a far more significant career. Courses in Western civilization were invented during World War I to explain to draftees what they were fighting for. These survived the war in a few American colleges, and spread widely in the 1930s, supplementing American national history and becoming required introductory courses for a great many students. Western “civ” courses retained that privileged status until the 1960s or later so that a whole generation of college students acquired a modest familiarity with ancient, medieval, and modern European history, and the belief that they were heirs of that past. This was accompanied by almost total ignorance of the history of the four-fifths of humankind excluded from Western civ courses.

Reasons for this curricular development are not far to seek. American national history was too brief to connect directly with ancient Greece and Rome, the staple of humanistic higher education as transmitted to the country’s Founding Fathers. Filling the gap with British history was acceptable to many Americans of English and Scottish descent, but Americans whose ancestors had come from other parts of Europe wanted a broader-based past and found it in “Western civilization” courses. And by annexing Western civilization to their own national history, Americans achieved a grander, more inclusive cultural ancestry than any single European country could boast.

There was a second and in many ways more powerful intellectual impetus behind Western civilization courses as they came on stream in the 1930s. Most college-bound Americans had learned a smattering of Biblical history in Sunday school, and the Christian (and Jewish) view that God governed the course of events was firmly implanted in their minds. But ever since the eighteenth century, a contrary liberal Enlightenment view of history had taken root in a limited intellectual circle, according to which the progress of liberty was what mattered most, and liberation from religious error by recognizing historical

causes with which God had nothing to do was part of the story.

Western civ courses offered a splendid opportunity to juxtapose these rival worldviews. By pitting Reason against Faith, “Saint Socrates” against Saint Paul, such courses spoke to central concerns of generations of students. Choosing to focus on a few great books, works of art, and big ideas—and showing how they changed from age to age—introduced college students to aspects of the Western cultural heritage and invited them to pick and choose what to accept and what to reject from it. As such, Western civ courses came alive for innumerable college students and helped them to

A menu for dinner served aboard a Hamburg-Amerika Linie steamer shows how French and English customs, like the musical “salon,” influenced German and American polite society for several centuries. New York Public Library.

shape a meaningful world from which the majority of humankind was tacitly excluded.

By the 1960s this constellation of circumstances altered, and Western civ courses soon lost their preferred place in most American colleges. Their dismantlement arose mainly from the discontent of young instructors who objected to teaching hand-me-down Western civ instead of presenting their own up-to-date specialized fields of research, as tenured professors preferred to do. Since tenure depended on published research it was clear that teaching Western civ delayed professional advancement. Tenured professors could not deny that obvious fact, so such courses had few defenders and most of them were soon scrapped.

Changes on the religious scene also contributed to making them obsolete. Decaying Sunday School training deprived Western civ courses of their earlier intellectual bite for some students, and a contrary current of born-again religious commitment made secular history unwelcome to others. Efforts to expand the scope of Western civ to embrace the rest of the world remained weak and sporadic and have not yet become really respectable in the eyes of most academic historians. Instead, industrious researchers multiplied specialties, making national history more and more incoherent, and calling the validity of every sort of statement about large-scale history into ever more serious question.

The collapse of European empires after World War II and widespread rejection of claims to any sort of ethnic, racial, or cultural superiority was a third factor that undermined the legitimacy of Western civ courses. And as students of non-European descent began to show up in college classrooms, efforts to accommodate them by teaching Amerindian, Asian, Latin American, and African history

multiplied. Multiple civilizations, all conceived as equal and separate, became fashionable; and when outsiders intruded, as Europeans had done so obviously in the nineteenth century, they were often blamed for it. Western civ thus became something of a bogeyman—the exact opposite of what American undergraduates had been brought up to believe between 1930 and 1960.

Further transformations of American historical teaching no doubt lie ahead. Western civ is likely to continue to play a conspicuous part as it has since the 1930s, because how to fit Europe as a whole and Western Europe in particular into the recent history of the world remains so problematic. Yet the whole concept of Western civilization as an entity acting in world affairs is uncertain. Structuring world history around separate civilizations became commonplace after Oswald Spengler's *The Decline of the West* (1918–1922) and Arnold J. Toynbee's *A Study of History* (1934–1961) did so. But as globalization advances, the separateness of local civilizations blurs, and historians, reflecting their times, have begun to emphasize larger, transcivilizational connections, while simultaneously questioning the coherence of Western or any other regional civilization.

Wind Energy

Sails were one of the first inventions to convert wind energy into motion, and windmills have been used since the tenth century to harness the power of the wind for grain milling and water pumping. In the early twenty-first century, wind is the fastest growing renewable energy source, forecasted to provide 20 percent of the world's electricity by the year 2040.

Only a small portion of incoming solar radiation (less than 2 percent) powers the atmospheric motion. The combination of diurnal and seasonal changes of insolation (exposure to sun's rays) and of differential heating of surfaces (vegetated vs. barren, land vs. water) mean that wind frequencies and velocities range from prolonged spells of calm to episodes of violent cyclonic (rainstorms, tornadoes, hurricanes) flows. Sail ships, used by the earliest civilizations of the Old World, were undoubtedly the first converters of wind energy into useful motion. And before the end of the twentieth century, one of the world's oldest energy sources has become one of the most promising modern providers of renewable energy as wind-generated electricity has been the fastest growing segment of modern renewable energetics.

The first written record of windmills comes a millennium after the first mention of water wheels: al-Masudi's report of 947 CE notes the use of simple vertical-shaft windmills in Seistan (in today's eastern Iran) to raise water for irrigating gardens. The first European record comes only from the closing decades of the twelfth century. Subsequent development of windmills was uneven in both time and space.

Windmills and Their Uses

The earliest vertical designs were used basically unchanged for many centuries in the Near East, as were the horizontal European machines. These mills pivoted on a massive central post that was supported usually by four diagonal quarterbars, and the whole engine house had to be turned to face the wind. Post mills were unstable in high winds and vulnerable to storm damage, and their low height limited their efficiency. Still, unlike China and India, where wind power made historically little difference, post mills became a major source of rotary motion in Atlantic Europe.

As with watermills, grain milling and water pumping (the Dutch drainage mills being the most prominent examples of this application) were the most common applications of wind power. Other common uses included grinding and crushing, papermaking, sawing, and metalworking. Post mills were gradually replaced by tower mills and smock mills. Only the top cap of these machines had to be turned into the wind, and after 1745 the English introduction of the fantail made it possible to turn the sails automatically. The fantail catches the wind bearing away from the sails and it turns the cog ring at the top of the tower until the sails are returned square on to the wind. More than a century before this innovation the Dutch millers introduced the first relatively efficient blade designs that provided more lift while reducing drag. But true airfoils, aerodynamically contoured blades with thick leading edges, were introduced in England only by the end of the nineteenth century.

America's westward expansion on the windy Great Plains created demand for smaller machines to pump

Windmill on Hay Ground Hill, Long Island, New York (1922). Windmills of this traditional design, unchanged for centuries, were most often used for grain milling and water pumping. Photo by Eugene L. Armbruster, New York Public Library.

water for steam locomotives, households, and cattle. These windmills were made of a large number of fairly narrow blades or slats that were fastened to solid or sectional wheels, and they were usually equipped with independent rudders and either the centrifugal or the side-vane governor.

Windmills reached the peak of their importance during the latter half of the nineteenth century: in 1900 about thirty thousand machines with a total capacity of some 100 megawatts worked in countries around the North Sea, and the U.S. sales of smaller brands of American windmills amounted to millions of units during the second half of the nineteenth century.

Wind Electricity

Many machines that continued operating in the twentieth century were connected to generators to produce electricity for immediate household use and

for storage in lead-acid batteries. Gradual extension of electricity networks ended this brief era of wind-generated electricity and little research and even less field testing on converting wind into useful energy was done until the early 1970s, when the Organization of Petroleum Exporting Countries (OPEC) suddenly quintupled the price of crude oil, reigniting the interest in renewable energies.

Modern Wind-Driven Electricity Generation

The first modern boom in wind energy was launched by U.S. tax credits during the early 1980s. By 1985 the country's wind turbines had installed capacity of just over 1 gigawatt, and the world's largest wind facility (637 megawatts) was at Altamont Pass in California. Low load factors, poor turbine designs, and the expiration of tax credits in 1985 ended this first wind wave. Better turbine designs, with blades optimized for low speeds, and larger turbine sizes have led the expansion that began around 1990. The average size of new machines rose from a mere 40–50 kilowatts in the early 1980s to over 200 kilowatts a decade later, and today's typical sizes in new, large wind farms are 1–3 megawatts (one megawatt equals 1 million watts, or one thousand kilowatts). Germany, Denmark, and Spain have been the leaders of this expansion. New laws that guarantee a higher fixed price for wind-generated electricity have been essential, and the Danish government has been particularly active in promoting wind power: the country now has the highest per capita installed capacity, and it dominates the world export market in efficient wind turbines. Germany is the world leader in absolute terms, and by 2007 Europe had about 60 percent of the globally installed wind capacity.

Wind-generating capacity in the United States rose from 1 gigawatt (1 billion watts) in 1985 to 2.5 gigawatts by the end of 2000, and it reached 20 gigawatts by September 2008. Global capacity of wind turbines reached 1 gigawatt in 1985, 10 gigawatts in 1998 (equal to nuclear plants in 1968), and 17.4 gigawatts in 2000, and then it grew rapidly to 59.1 gigawatts

I was born on the prairies where the wind blew free and there was nothing to break the light of the sun. I was born where there were no enclosures. • **Geronimo (1829–1909)**

by 2005 and to nearly 94 gigawatts by 2008. As a result wind-driven electricity generation is seen as the most promising of all new renewable conversions, far ahead of other solar-based techniques both in terms of operational reliability and unit cost. Some experts argue that at the best windy sites, even unsubsidized wind electricity is already competitive with fossil-fueled generation, or even cheaper than coal or gas-fired production, and hence we should go for a more aggressive maximization of wind's potential. Some plans foresee 20 percent of the world's electricity demand generated by wind by the year 2040, and 20 percent of America's electricity coming from wind by 2030. That is not a modest goal considering that in the year 2000 wind generation produced just 1 percent of the country's electricity.

Available resource is no obstacle to even the boldest dreams. Only about 2 percent of all solar energy received by Earth is needed to drive the atmospheric motion, and if a mere 1 percent of this flux could be converted to electricity, the global capacity would be some 35 terawatts (one terawatt equals 1 trillion watts), or more than ten times the 2000 total installed in all fossil, nuclear, and hydro stations.

A much more restrictive estimate that considers only wind speeds above 5 meters per second up to 10 meters above ground puts the global wind power potential at about 6 terawatts, or about 350 times larger than the total installed in 2000. The main problems associated with tapping this potential result from the fact that wind is unevenly distributed in both space and time.

Many windy sites are far away from centers of electricity consumption, and many densely populated areas with high electricity demand experience long seasonal periods of calm or low wind speeds and hence are utterly unsuitable, or only marginally suited, for harnessing wind's energy. Virtually the entire southeastern United States, northern Italy, and Sichuan Province (China's most populous province) are in the latter category. Wind's intermittence means that it cannot be used for base-load generation. Its fluctuations are only imperfectly predictable, and peak wind flows only rarely coincide with the time of the highest demand. Inevitably, these realities complicate efficient commercial utilization. The visual aspect of siting large turbines and building connection and transmission lines is another concern. Offshore

A wind farm in California. These modern-day windmills are used to generate electricity. Photo by Kevin Connors (www.morguefile.com).

siting of wind turbines should help to minimize or eliminate these impacts.

Women and Literature

Although the world's earliest-known writer (Enheduanna, c. 2300 BCE) was a woman, women's literature has largely been disregarded and trivialized, at least until the twentieth century's feminist wave focused attention on it. From ancient Greece's Sappho to contemporary authors of the developing world, the subjects, styles, and stories are varied; women's literature, however, often does challenge boundaries and confront oppression.

Historically, women have both penned and been the subject of literary works since ancient times, but their relationship to the literary realm has been mediated by their struggle to become literate—to be able to write, read, and critique literary works—and by their insufficient participation in the production process. As objects under the male gaze, they have largely been stereotyped or downright ignored, rarely presented as autonomous agents of history. Furthermore, women writers historically have been marginalized by their male counterparts, and many of their works either remain unacknowledged or tokenized by literary critics. With the rise of the global women's movement, and the feminist movements in the West in the last millennium, male and female scholars alike are rediscovering and celebrating foundational works of women's literary production from ancient times to the present.

Ancient Women Writers

Some of the earliest writings and evidence of women's literacy have been found in excavations of the ancient cities and cultural centers of Egypt, Mesopotamia,

Greece, Asia, and the Americas. The earliest known female writer, and the earliest known author of all literature, Enheduanna, lived and wrote around 2300 BCE, almost two thousand years before the “Golden Age” of Greece, in what we know today as the Middle East. She was an Acadian (at the time part of what is present-day Iraq) writer, priestess, poet, and princess, daughter to King Sargon I of Akkad, who created the first historical empire. The paucity of writing about this important author and poet as well as her exclusion from world literature and women's literature anthologies is not surprising given that her works have only recently resurfaced. All of the artifacts upon which translations of Enheduanna's work are based come from the Old Babylonian period nearly a half millennium after her existence and include at least two and possibly three major hymns directed to the goddess Inanna, the goddess of battle. These works were rediscovered in excavations at Ur in 1921, but the first translations of her work into English did not occur until 1968 when W. W. Hallo and J. J. Van Dijk translated *The Exaltation of Inanna* by Enheduanna. More recently, the German scholars Annette Zgoll and C. Wilcke have separately identified up to forty-nine newly publicized texts, resulting in a new, updated translation by Zgoll.

Although no evidence has been unearthed so far of literary works written by ancient Egyptian women, they did have a goddess of writing—the goddess Seshat, the “female scribe.” Other than Seshat, very few women were depicted with a scribe's writing kit in the surviving scrolls, as the preferred writing medium of papyrus has not endured the passage of time like the clay tablets of Mesopotamia. The high-ranking or royal women who were literate were often given a

Sir Lawrence Alma-Tadema, *Sappho and Alcaeus* (1881). Oil on canvas. This painting re-creates a scene preserved in Book 2 of Athenaeus' *Deipnosophistae* (Philosophers at Dinner), in which Sappho and her companions listen to the poet Alcaeus play the *kithara*. Alma-Tadema accurately depicts the marble benches at Athens' Theater of Dionysus but substitutes the names of Sappho's sorority members for those of the city officials that were incised on the prototype.

private tutor who taught them reading and writing. For example, Neferura, the female pharaoh Hatshepsut's (reigned 1503–1482 BCE) daughter, had a private tutor, Senmut. Excavations in Egyptian tombs have provided evidence that at least some ordinary housewives were able to read and write—there were laundry lists, female fashion advice, and other female concerns found in preserved papyrus scrolls. A detailed history of the role of women in ancient Egypt is provided in *Mistress of the House, Mistress of Heaven: Women in Ancient Egypt* (Capel, Markoe, and Markoe 1977).

The Greek poet Sappho is one of the most well-known female poets of all time. She was born toward the end of the seventh century BCE, during the Greek Archaic Period. A native of Mitylene in the island of Lesbos, Sappho was one of the two (with Alcaeus) great leaders of the Aeolian school of lyric poetry. She was widely acclaimed for the originality of her brilliant lyric poetry and lived to be honored by her

people for her literary gift. Poetry in her day was usually accompanied by music and dance, and Sappho was so accomplished at composing in all three modes that she acquired a reputation for being the divine inspiration of the muses; she was even referred to as the tenth muse. The debate and speculation about her expression of strong passion toward other women has been the subject of many articles, books, presentations, conferences, and even websites. But in Sappho's society, as in later pre-Freudian eras, women often congregated and, among other social activities, shared the poetry they had written, and their open expression of love and passion toward one another, whether sexual or not, was acceptable and commonplace. Her lyric poems formed nine or ten books, but only fragments of these have weathered the ages, and no piece is longer than sixteen lines. The most important is an ode to Aphrodite, which may be the most complete of the works that have survived.

The first recorded female playwright, Hroswitha of Gandersheim, was born in 932 CE to the Saxon aristocracy. She became a Benedictine cloister nun early in life and was known for her witty and farcical plays. A century later, Anna Comnena became the first female historian. Born in 1083, Comnena detailed the reign of her father, Alexius I, and the exchanges between the Byzantines and western crusaders of the first crusades in her fifteen-volume history of her family, titled *Alexiad*. Comnena lived in an era when women chiefly were expected to remain secluded in their quarters (called *gynaeceum*) attending solely to family matters. They covered their faces with veils in public and were not even allowed to appear in processions. In her writings, however, it is evident that she was allowed to express her own thoughts and serve an important role in preserving her family's history.

In the realm of theology, composition, and visionary writing, Hildegard von Bingen, born in 1098, published the visionary *Scivias*. Known as "Sybil of the Rhine," she was highly revered for her treatises about natural history and medicinal uses of flora and fauna as well as minerals and stones. She founded several convents, and is the first composer whose biography is known. She has been beatified and is often referred to as Saint Hildegard. She wrote, composed, and was a respected leader and wise woman at a time when few women were accorded these privileges.

Japanese writer Murasaki Shikibu is credited with writing the world's oldest novel and one of the finest, *The Tale of Genji*. Written in the Heian period (794–1185) in Japanese history, during the early eleventh century, when prose and poetry by women scarcely existed in the West, the work followed a tradition of romances depicting life among the court nobility of Japan. Shikibu was born into the Fujiwara family, daughter of the governor of a province, who was a well-known scholar. He allowed Shikibu to study with her brother, even letting her learn some Chinese classics, which was considered improper for females at the time. In its length (more than one thousand pages in

Kano Tannyu (n.d.). Woodcut print portraying Murasaki-Shikibu, author of *The Tale of Genji*.

the English translation), complexity, realism, psychological depth, and literary distinction, *The Tale of Genji* is considered a masterpiece of Japanese literature.

History, real solemn history, I cannot be interested in . . . I read it a little as a duty; but it tells me nothing that does not either vex or weary me. The quarrels of popes and kings, with wars and pestilences in every page; the men all so good for nothing, and hardly any women at all—it is very tiresome. • Jane Austen (1775–1817), as Catherine Morland in *Northanger Abbey*

The First Feminists

With the publication of her poetry in the fourteenth century, poet and philosopher Christine de Pisan became the first woman to earn her living through writing. She is widely believed to be the first feminist writer in the history of literature. Many of de Pisan's works urged that women be allowed to participate more fully in society. She also denounced the way women were portrayed in medieval literature. For example, in her long poem *Letter to the God of Love*, she complained that women were often described as dishonest and unreliable. She openly criticized misogynous literature in a controversial debate known as the *Querelle des Femmes*, a debate which is thought to have also inspired many British women writers who came after her.

Indeed, British women writers argued strongly for women's literacy, even as they were forced to use pen names so as to avoid scandal. The first known feminist argument published in English is credited to one Margaret Tyler, whose true identity remains a mystery. In 1578, Tyler argued that women have the same capacity to research and write as men do, and that they should be allowed not only to write, but also to choose their own subjects. A decade later, in 1589, another writer whose identity is still unclear but who went by the pen name of Jane Anger became the first major female polemicist in English. In a lengthy tract called *Jane Anger: Her Protection for Women* (1589), she challenged the misogyny present in Elizabethan culture and asked, "Was there ever any so abused, so slandered, so railed upon, or so wickedly handled [*sic*] undeservedly, as are we women?" Other "First Feminists," as the scholar Moira Ferguson calls them, include Aphra Behn, the first female British playwright and a spy for the British government; Mary Collier, author of *The Woman's Labour* (1739); Ann Cromartie Yearsley, author of "A Poem on the Inhumanity of the Slave-Trade" (1788); Catherine Sawbridge Macaulay Graham, who in 1790 published *Letters on Education*; and the most influential British feminist thinker of her time, Mary Wollstonecraft, who said, "It would be an endless task to trace the variety of meanness,

cares and sorrows, into which women are plunged by the prevailing opinion, that they were created to feel than reason, and that all the power they obtain, must be obtained by their charms and weakness." Wollstonecraft advocated for a more humanitarian approach to Native American Indians, and in her *A Vindication of the Rights of Man* (1793), she attacked slavery as well. Her persuasive and passionate call for human justice is exemplified in her most famous work, *A Vindication of the Rights of Woman*, written in 1792.

Following in the line of daughters of the nobility around the world who had access to literacy, the Indian poet Mira Bai, a devotee of Krishna and a princess who renounced her royal family, was the only female among the sixteenth-century Bhakti poets. Her poems celebrate women's songs and folk traditions, and are often directly addressed to a female friend or an audience of women. At a time when infringement of the rules of chastity, modesty, and seclusion for married women was an insult to the family of a noblewoman, her writings showed a remarkable sensuality and were considered to be quite subversive.

In the Americas, there is also a rich history of women authors that has only recently begun to be rediscovered and celebrated. Societal and cultural attitudes resulting from the legacy of colonization, genocide, forced destruction, and undermining of indigenous people's traditions and values have led to a literary canon that is characterized by the inadequate representation of female-authored works. Of the autonomous ancient peoples of Mesoamerica (i.e., central and south Mexico, including the Gulf Coast, the Yucatan Peninsula, Guatemala, and parts of El Salvador and Honduras, the general area where high civilizations flourished between 1000 BCE and 1521 CE), it is the Aztec princess Macuixochitl "5-Flor" (5-Flower) who stands as the lone female voice in a rare compilation of poems by thirteen Aztec poets published by Don Miguel León Portillo, Mexico's leading indigenous scholar, in the 1960s. Daughter of the great adviser to seven Aztec emperors, Tlatoani Tlacaelel, Princess Macuixochitl

5-Flor exemplifies the high status that the daughters of the ancient Aztec nobility could achieve. Hers is so far the only female literary voice that remains from precolonial Mesoamerican history, even though there are several chronologies of the conquest that provide a secondhand portrayal of women and their experiences in colonial America. Of these representations, perhaps the most famous in Latin America and in world literature is the figure of La Malinche, an Indian woman who served as interpreter, guide, mistress, and confidante to the Spanish invader Hernán Cortés during the time of the conquest. Considered by some as the first woman of Mexican literature—and by most Mexicans before the modern period as a traitor, prostitute, and symbol of national betrayal—her story has been the topic of countless and oftentimes contradictory descriptions and interpretations and, with the rise of Chicana and Mexicana writers and critics such as Adelaida R. Del Castillo, Cherrie Moraga, and Elena Poniatowska in the twentieth century, of more positive reconfigurations.

The first feminist, and undoubtedly the greatest poet of the Americas in the seventeenth century, the Mexican poet Juana Ines de la Cruz, was born in 1651 in San Miguel Nepantla, a village south of Mexico City. Her given name was Juana Ines Ramirez. She was a Jesuit nun, a woman of genius whose ideas and accomplishments were ahead of her time. With works like *Respuesta a Sor Filotea* (Response to Sor Filotea), *Protesta Que Rubrica con Su Sangre* (Profession of the Faith Signed with Her Own Blood), and *Carta Atenagorica* (The Athenagoric Letter) Sor Juana, a Jesuit nun, became the first woman in the Americas to speak out against the injustices done to women and called for their education. She wrote amazing lyrical poetry, of which her most famous are her *Redondillas*. She also wrote comedic plays that criticized the passive role that was expected of women in the Middle Ages, and challenged the female archetypes in medieval literature. Her secular poetry, her rhetoric, music, plays, and pursuit of scientific knowledge were unheard of in her society, especially by a nun, and she was in the end censured for her analysis of a sermon given by a Jesuit priest she disagreed with. When she

Miguel Cabrera, *Sor Juana Inés de la Cruz* (1750). Oil on canvas. Juana Ines Ramirez, who became a Jesuit nun, fought against female archetypes in medieval literature and was eventually censured for disagreeing in writing about a priest's sermon.

refused to stop writing secular works, she was forced by the archbishop to turn over her books, scientific instruments, and other possessions, and died alone of an unknown epidemic that swept her convent. She is often compared to the Greek poet Sappho and has influenced countless women writers after her.

The 1800s and Early 1900s

The late eighteenth and nineteenth centuries saw a proliferation of publications by women. After centuries of calling for greater access to literacy and education, to legal rights and labor rights, the international women's struggle for human and civil rights intensified and reached new heights. An influential group of American women, including Elizabeth Cady Stanton and Lucretia Mott, composed the "Declaration of Sentiments and Resolutions," outlining the main issues and goals for the emerging women's movement,

at the First Women's Rights Convention at Seneca Falls, New York, in 1848. The first gains in the international suffragist movement earned women the right to vote in countries like Sweden (1862, in local elections), Scotland (1881, local elections), and New Zealand, which became the first and only country to allow women to vote before the end of the nineteenth century, in 1893. In the United States, at the same time when Southern white women created Confederate memorial societies to help preserve the memory of the "Lost Cause," newly emancipated Southern black women formed thousands of organizations aimed at "uplifting the race." Then, in 1866, Elizabeth Cady Stanton and Susan B. Anthony formed the American Equal Rights Association, an organization for white and black women and men dedicated to the goal of universal suffrage. It was in this environment of division and cooperation that African-American women's writings began to proliferate. The works of these writers spanned several literary genres, including poetry, essays, short stories, histories, narratives (including slave narratives), autobiographies, novels, theological works, social criticism, and economic and philosophical treatises. Although the first known book of poetry by an African American, *Poems on Various Subjects, Religious and Moral* by Phillis Wheatley, appeared in 1773, it was not until the mid-nineteenth century that novels like Harriet Beecher Stowe's *Uncle Tom's Cabin* (1852) and *Our Nig* by Harriet Wilson (1859) appeared. This is perhaps due to the fact that before the Civil War, most people of African descent were held in bondage in the United States. Sojourner Truth once remarked, in reply to an allusion to the late Horace Greeley, "You call him a self-made man; well, I am a self-made woman." Indeed, what may be considered the first testimonial work by an African American woman, *The Narrative of Sojourner Truth: A Northern Slave*, a dictated memoir by Sojourner Truth, was published in 1850, and the first collection of essays by an African American, Ann Plato's *Essays*, was published in 1841.

Other important African American women writers include Harriet Jacobs, Nancy Prince, Elizabeth Keckley, and Ellen Craft. Jacobs, who was born in 1813 and wrote the most in-depth pre-Civil War slave

narrative written by an African American woman in America, published her *Incidents in the Life of a Slave Girl* in 1861. The book was thought to be written by a white woman until the rediscovery of Jacobs's works in the 1980s, as she had not used people's real names and claimed the pseudonym Linda Brent for herself in the narrative. Nancy Prince, who published *Narrative of the Life and Travels of Mrs. Nancy Prince* in 1850, provided the first autobiographical account of life as a free black woman in antebellum America. It is also an important contribution to the genre of autobiographical travelogues, since she documents her travels to Russia, Jamaica, and different parts of the United States over the course of eighteen years and provides a firsthand account of the 1824 flood of St. Petersburg, the deaths of Emperor Alexander I and Empress Elizabeth, and the Decembrist Revolt of 1826. Elizabeth Keckley, who wrote *Behind the Scenes, or, Thirty Years a Slave and Four Years in the White House* as a personal account of life in the White House, challenged the predominant stereotypes of women, and African American women in particular, in the nineteenth century. A friend and confidante of Mary Todd Lincoln, she was highly criticized for claiming that she was a friend of a white woman, and the wife of a president at that. The oldest son of President Lincoln, Robert Lincoln, waged a campaign against the book, and was successful in having the book withdrawn from publication. She went on to found a school for young black girls in 1863, was president and founder of the First Black Contraband Relief Organization, and represented Wilberforce University at the 1893 Columbian World's Exhibition in Chicago. Ellen Craft's amazing account of her and her husband's escape from slavery, *Running a Thousand Miles for Freedom*, is considered to be "one of the first examples of racial passing, cross-dressing, and middle-class performance in a society where each of these boundaries were thought to be distinct and stable" (Brusky 2000). Craft dared to use her light skin to pass as a white male in order to travel by train and boat, with her husband William Craft posing as her slave. Their escape, and particularly Ellen's disguise, illustrates the interlocking nature of race, gender, and class, for Ellen's passing had to be

Literature is my utopia. • **Helen Keller (1880–1968)**

successful in all three arenas simultaneously in order for them to travel undetected. And since William's narrative voice actually tells the story, *Running* also shows how difficult it was, even for a woman bold and daring enough to escape slavery in this way, to find a public voice as a black woman. Indeed, like her disguise, which involved poultices that "muffled" her and allowed her to avoid conversation, Ellen's voice is given through the filter of William's perspective.

The mid-nineteenth century also saw the publication of one of the earliest precursors to contemporary Chicana (Mexican-American) literary tradition. With the publication of her novels *Who Would Have Thought It?* in 1885 and *The Squatter and the Don* (under the pseudonym C. Loyal) in 1872, Maria Amparo Ruiz de Burton became the first writer to publish a novel from the perspective of the Californios, the dispossessed population living in Alta California at the end of the U.S. invasion of Mexico that began in 1846 and ended with the Treaty of Guadalupe-Hidalgo in 1848. Ruiz de Burton's novels and personal writings provide a scathing condemnation of the new rulers and the forms of ruling imposed upon the conquered population and give balance to mainstream histories of this period of American history.

In Spain, the nineteenth century produced the most celebrated female author of her time, and arguably one of Spain's most important literary figures. Emilia Pardo Bazan, born in 1852, was a Spanish countess who wrote over five hundred short stories and essays, more than forty novels, and seven plays. She also edited and published several magazines in her lifetime, including *La Revista de Galicia* and *Nuevo Teatro Critico*, and in 1892 founded La Biblioteca de la Mujer (The Woman's Library). Having had her first work published at the age of eight, she won many awards, perhaps the most notable of which was the *Crux Pro Ecclesia et Pontifice* (Cross for the Church and Pontiff), which she received from Pope Benedict XV. Of all her works, perhaps her best known piece is *La cuestión palpitante* (*The Critical Issue*), written in 1883. A polemical essay that discusses naturalism, it introduced the French and Russian literary movements to Spain and started an important literary

controversy in which she championed the free will of the individual. In 1916 she became Professor of Contemporary Literature at Central University of Madrid, a position created solely for her.

Born in 1882, Adeline Virginia Stephen, or Virginia Woolf, is credited with developing a new kind of prose that she associated with female consciousness and with her precise evocations of states of mind and body; thus she joined Marcel Proust and James Joyce in a move away from the conventions of modernist realism and linear plot to a more complex ordering of her narratives, including juxtapositions of diverse points of view, incomplete perspectives, and time and space displacement. *A Room of One's Own*, perhaps her most famous work, examines the history of literature written by women and argues for women's

Studio photograph of Virginia Woolf (1882–1941) taken in 1902 by George Charles Beresford. Woolf's *A Room of One's Own* became an icon of feminist literature.

Maya Angelou recites her poem, "On the Pulse of Morning," at President Bill Clinton's inauguration, 19 January 1993. Office of the White House.

economic independence and the privacy of a room in which to write. Originator of the Bloomsbury Group, she was a successful publisher, founding Hogarth Press in 1917 with her husband, Leonard Woolf. She was also an activist in the suffrage and feminist movement, and taught as a volunteer at Morley College, which provided educational opportunities for workers, although her weak health and severe bouts of depression and mental illness plagued her until 1941, when she committed suicide.

Contemporary Women Writers

The French writer Simone de Beauvoir, with the publication of her book *The Second Sex* in 1953, is considered by some to have inspired the second wave of the feminist movement with her in-depth discussion of women's oppression and of their role as "other." Indeed, her comprehensive treatise on women weaves together history, philosophy, economics, and biology and postulates on the power of sexuality. The 1970s and 1980s were enormously important in feminist

literary theory and women's studies, with major contributions by Helene Cixous of France, Teresa De Lauretis of Italy, Belgium's Luce Irigaray, Donna Haraway of the United States, Bengali exile Gayatri Chakravorty Spivak, and Julia Kristeva of Bulgaria, among others. Then, in the late 1980s, women of color and Third World women such as Kumari Jayawardena of Sri Lanka, Chandra Talpade Mohanty of India and the United States, Ella Shohat of the United States, Paula Moya of the United States, Lata Mani of India, Trinh T. Minh-ha of Vietnam and the United States, Gloria Anzaldua of the United States, and Cherrie Moraga of the United States published powerful writings that theorized, challenged, dialogued with, and expanded discussions of feminist theory, gay/lesbian/queer/black feminist theory and Chicana/Latina feminist theory, and enriched the fields of postcolonial and Third World women's literature.

Women writers in the twentieth and twenty-first centuries have continued to speak out against oppression, to redefine the boundaries of what are considered acceptable literary forms and subjects, and to gain more widespread recognition of their works. But the literary canon is still in great need of revision that must insist upon the incorporation of women writers who have been ignored and omitted from literary history. One example of a text that follows this ideal of equality and inclusiveness is Shirley Geok-Lin Lim and Norman A. Spencer's *One World of Literature*. This amazing anthology, originally published in 1993, offers an impressive array of twentieth-century male and female authors, and one of the most complete collections of full texts and excerpts by women writers from around the world. Highlighting the works of a diversity of writers like Bessie Head of Botswana, Rosario Ferré of Puerto Rico, and Jamaica Kincaid of Antigua, this anthology is essential reading for anyone interested in women in world literature. The anthology represents the works of brilliant female authors seldom known outside their own countries as well those known worldwide. The works of Ama Ata Aidoo of Ghana, Fawziyya Abu-Khalid of Saudi Arabia, Wang Xiaoni and Ding Ling of China, Ambai and Amrita Pritam of India, Ishigaki Rin of Japan,

Shirley Geok-Lin Lim (the editor herself) of Malaysia, Elizabeth Jolley of Australia, and Margareta Ekstrom of Sweden are coupled with those who have achieved a wider international reach, such as Nobel Prize winner Nadine Gordimer of South Africa, Mahasweta Devi of India, Zhang Ailing of China, Isabel Allende of Chile, and Margaret Atwood of Canada. According to Shirley Geok-Lin Lim and Norman Spencer, “we live in an age in which an understanding of global cultures is more critical than ever. . . . [W]e are all affected by individuals, events and ideas from other cultures and countries, a truth the late twentieth century has brought home to almost everyone” (Lim and Spencer 1993, xv). It is with this spirit in mind that works such as theirs are beginning to bring balance to a literary world where women’s literacy, women’s writing and its assessment, and the representation of women as autonomous subjects has tended to suffer under the weight of homogeneity, unilateralism, patriarchy, ethnocentrism, and the Western gaze.

Women's and Gender History

During the early nineteenth century, history was written about nations and politics, and the role of men was emphasized. In the 1960s—inspired by the women's movement—a new interest in women's history developed; many asked how the history of women could be separated from economic, social, political, and ideological history. Women's and gender history can provide a new perspective about society and the past.

Women's and gender history may be defined as the history of relations between women and men, of the changing understanding of femininity and masculinity, and of the importance of gender in the organization of society. Since any society, anywhere and at any time, consists of women and men, gender interacts with other categories, such as race, ethnicity, class, citizenship, nationalism, imperialism, and religion, and with other value systems. It assumes importance in divisions of labor as well as in cross-cultural encounters throughout time and has served as a trope for hierarchical perceptions of cultures and power relations.

Gender perspectives in world history date back at least to Enlightenment world histories. At the end of the eighteenth century, some historians focused on costumes and manners, and on peoples' ways of life. Some works pointed to the importance of material conditions, as well as to religious and political systems, for defining women's status; some compared the lives of women within different cultures; some even characterized non-European people as feminine and implicitly less civilized. But when, in the early nineteenth century, historical research narrowed to national histories, mostly concentrating on political

history, the question of gender was left to be explored by other disciplines, such as social anthropology and sociology. In the 1960s, universal history again attracted attention, mainly in the United States. By then historical research was being criticized for neglecting women and seeing men as universal representatives of humankind. Inspired by women's movements and by new approaches to historical studies, such as the history of mentalities, demographic history, and family history, the interest in women's history now blossomed at the national level. During the 1990s this approach also made itself felt within the growing field of universal history.

The Theoretical Framework

Most historical research rests on a dichotomous understanding of gender; an individual is seen as either a woman or a man. Some also take for granted that biology determines not only the sex of a person but also the gender. Historians have challenged this dichotomy by investigating the historical understanding of sexual differences. Departing from Aristotle's assumption of the existence of only one sex, which sees women as embryonic, unfinished males, passing by the dichotomy created by Christianity that equates men with spirituality and women with materiality, they have traced the rise of the two-sex model from the end of the eighteenth century, reaching an apogee through Darwinism and the medical sciences, and experiencing a recent rebirth with sociobiology.

Anthropology and cross-cultural history have cast doubts on this dichotomous understanding of gender. In many parts of the world, notably Africa, but also Alaska, the Amazon region, and parts of Asia,

individuals have assumed tasks, behavior, and clothing that might be seen as characterizing the opposite sex. Some cultures have seen age as determining gender, understanding children and old people as belonging to different genders than grown-up males and females. Add to this the study of gay and lesbian history and the history of sexualities, and it will be understood that world histories need to be aware of variations in the understanding of femininity and masculinity.

An increasing number of studies have shown that systems of sexual differentiation affected both women and men. These revealed the need to study the history of men, too, as gendered individuals. A distinction between sex (that is, physical anatomical differences) and gender (that is, culturally and historically constructed differences between women and men) started the argument over essentialism versus constructionalism. In the 1990s queer theory and poststructuralism further diversified approaches to gender history. The linguistic turn, which focused on texts—literary as well as visual material—rather than on events, individuals, or groups also helped pave the way for studying gender as a trope for hierarchical relations in fields of history that at the outset seemed to have nothing to do with gender.

Some historians have feared that these approaches would deprive women's history of the possibility of studying women as agents in history and reduce the focus of history to the history of women's lived lives. The term *gender history* has also sometimes been seen as a departure from the original aim of restoring women to history and as weakening the political potential of women's history. Gradually, however, helped by the growth in interdisciplinary research approaches, such divisions have become less distinct. Gender history and men's history are now frequently seen as outgrowths of and parallels to women's history, and cultural studies have united a number of approaches to historical research.

Applying gender as an analytical category to world history may be a fruitful way to see gender as a process where the meanings and importance of gender

A woman and man from the Mosuo matriarchal society of Lugu Lake, Yunnan Province, China, in a traditional canoe. The Mosuo are among the few remaining matriarchal societies. Photo by Sara Gouvela.

may change over time, and where the importance of other analytical categories—ethnicity, race, class, national and cultural identity, and so on—may interact with gender in varying ways. Gender may be seen as a basic social structure that in any culture, in any society, and at all times interacts with other social structures to determine the socialization of an individual, the distribution of work and responsibilities, and of rights in the family and in society. Gender is at work in studies of material life as well as of ideologies and politics. When societies change, so do gender relations, and changes in gender relations influence other economic, social, and political relations.

From Matriarchy to Patriarchy?

A central issue in early global women's and gender history has been the question of the origin of patriarchy. Although most cultures overtly allocated more direct power to men than to women, historians have wondered if there was once a time when this was not so. Some have postulated the existence of prehistoric matriarchal societies in Africa, in the early Americas, and in Europe. The German nineteenth century scholar J. J. Bachofen (1815–1887) saw such societies as primitive ones that were gradually supplanted by patriarchies, which were more advanced. The socialist Friedrich Engels (1820–1895) believed that agriculture and private ownership gave rise to the nuclear family in which men controlled women's sexuality in order to ensure legitimate offspring.

Hans Baldung (1484–1545), *Adam and Eve* (n.d.). Oil on wood. Galleria degli Uffizi, Florence. The biblical story of Adam and Eve famously blames Eve for the couple's expulsion from paradise.

The American historian Gerda Lerner (b. 1920) has put forward the theory that patriarchy was based on the exchange of women among men and preceded other hierarchies. Other theories have examined the importance of men's physical strength and women's need for protection for the development of patriarchy, or they have interrogated the impact of religious and other ideological forces, of material structures such as plough-cultures, private ownership, literacy, and not least, of state formation and political systems on gender relations. Whatever the theory, insufficient source material makes it impossible to decide how male-dominated societies evolved. But the complicated structures of such societies and the variations among them through time remain enticing research areas.

Gendered Global Human Experiences

Applying gender as an analytical category means questioning the divide between the history of economic, social, political, and ideological structures

and the history of private lives. A basic question may be the shifting importance of the household and family unit to the development of any society. In fact, all global human experiences lend themselves very well to gender analysis. Family structures, economic and social life, politics and value systems, religion, education, and sexuality all vary with gender among cultures and over time to different degrees. A good example may be the gendered effects of twentieth-century population policies. While men and women alike were preoccupied with the family economy and the future of the nation, women experienced population policies on their own bodies. Technological and economic changes, such as the Industrial Revolution, were built on the existence of a gendered labor force and offered cheap routine female and male labor, as well as more expensive specialized, exclusively male labor.

The formation of nation-states and national identities also included women and men in different ways, burdening men with military protection, national expansion, and the economic success of the nation, and women with generational reproduction and the social upbringing of new members of the nation. While preindustrial societies sometimes lent women political power through family connections, for a long time “modernizing” democratic states allocated such power only to men. Regardless of class, ethnicity, or skin color, with very few exceptions women were the last group to obtain suffrage. Religious systems and other ideologies throughout time have contributed in various ways to uphold gender differences and gendered power relations.

Reconsidering Central Concepts

Gender analysis leads to the reconsideration of central concepts. The widely accepted definition of *work* as paid labor in the public sphere will need to be revised in order to include women's unpaid work in the family and household. The importance of this work, as well as the importance of a cheap female labor force, must be taken into consideration in any analysis of material life.

The concept of *power* must incorporate patriarchal power structures into class and race analysis, and consider the effect of psychological sources of power, such as an appeal to emotions, to chivalry, and to honor. Politics must be considered in a wider context than that of public authorities. Civil society as well as kinship must be taken into consideration.

Access—be it physical access to certain spaces or immaterial access to certain prerogatives such as education or political power—is another concept that may be useful for women’s and gender history. Why was women’s access to public spaces and even physical mobility more limited than men’s, and why and how did this vary with social standing and among cultures? The history of physical barriers, such as foot-binding, zenanas, and harems, as well as of the morally grounded limits to women’s mobility includes a gendered understanding of access. Needless to say, educational and political systems were molded in the same perception of gendered spaces. Why did some groups of both men and women struggle to continue such traditions, while others fought to eliminate them?

Special consideration may be given to the understanding of *identity*. Juggling gender, class, caste, ethnicity, and nationality may seem to dissolve personal identity. But analyzing situations where several identities are at play, the historian may ask what prompts one of them to take precedence over the others. Why would an individual at times act mainly as a woman, at other times mainly as a member of a certain social group or of a specific nation? How did gender influence class identity, and how did caste identity vary with gender?

In short, rethinking a number of concepts indispensable to historical analysis will bring forward a new and more varied knowledge of global human experiences.

Cross-Cultural Interactions

Gender played an important role in the meeting of different cultures—for example, the varied influence of Islamic understandings of gender in India and sub-

Jan van Eyck, *Giovanni Arnolfini and His Bride* (1434). Oil on wood. National Gallery, London. Under patriarchal systems in medieval Europe women were not allowed to own property, and their fathers or male relatives decided whom they would marry.

Saharan Africa from the eleventh century onwards, or the Chinese military expansion during the Tang and Song dynasties (618–907 CE and 960–1279, respectively), which spread a strict patriarchal culture to much of East Asia. Chinese-Mongol contacts, however, witnessed a reciprocal distaste for gender relations in the other culture and left little influence either way. Colonial and imperial contacts are the most explored cross-cultural meetings. Enlightenment world historians used gender as a trope for communicating cultural differences. They sometimes characterized non-European cultures not only as “hideous” and “dark-colored,” but also as exhibiting unsympathetic characteristics such as “more than feminine cowardice.” Later male colonizers could construct the notion of colonized women as representing “true femininity” since they served and obeyed men, in opposition to their Western counterparts, who increasingly

refused to do so and even demanded the same rights as men.

Ironically, women missionaries, in their ardent attempts to spread Western values and lacking a full understanding of the workings of gender in cultures other than their own, often encouraged Victorian feminine behavior in colonized women. They did this despite the fact that many of them had intentionally broken out of the limitations implied in Victorian ideals.

The Western understanding of masculinity was also at play. The British would perceive a physically strong and athletic male body and the capacity for self-control and restraint as necessary for those who intended to rule a nation. Seeing Bengali middle-class men as small, frail, effeminate, and lacking self-control, British officials might find them unable to govern themselves, let alone a whole society.

The interaction of changing understandings of gender provides an interesting approach to the study of cultural encounters. Growing opposition to British rule and Westernization strengthened the need for the family as a refuge for Bengali middle-class men. This paved the way for more education for women so they could become intelligent mothers and wives who would uphold Bengali historic traditions within the family. But in the long run this also led to the formation of Indian women's organizations, and for

a while, to cooperation between Indian and British women in the fight for women's suffrage. Repressive British policies at the end of World War I, however, damaged these cross-cultural contacts, and Indian women rebelled against being seen as young daughters to be educated by British protective mothers. The spread of Western feminism after World War II raised similar questions about cooperation and conflict among women.

Critical Dialogues?

As in so many other fields, the uneven growth of historical sciences around the world has implications for the gendering of world history. Women's and gender history first evolved in the United States and Canada, and was taken up soon afterward by Western European universities; the spread to Eastern Europe and to Asian, African, and Latin American universities was slower. But since many historians from these parts of the world are educated at American or European universities, Western research approaches and Western theories exert an overwhelming influence within women's and gender history all over the world.

Special awareness is needed when studying culturally contested historical phenomena, especially if they have an impact on today's societies. Among them are traditions such as sati (widow burning), veiling, and female genital mutilation. For a historian analyzing these traditions, it becomes especially important to distinguish between attempting to understand and explain behavior that is foreign, or sometimes even repulsive, and accepting such behavior; understanding is not the same as accepting. Historians may need to openly acknowledge their own limited cultural and class background, sometimes even their gendered background, in order to work at transgressing such limits. Subaltern (a term referring to those people socially, politically, and/or geographically outside of the existing power structure) studies like those in the 1980s have helped counteract the flood of Western histories. Dialogues have been encouraged by the trend to stop perceiving colonialism and imperialism exclusively as a polarization between the

The dogma of woman's complete historical subjection to men must be rated as one of the most fantastic myths ever created by the human mind. • **Mary Ritter Beard (1876–1958)**

metropolis and the colony and instead to highlight the interaction between what used to be seen as center and periphery. Critical dialogues among historians of various cultural backgrounds are multiplying at international conferences, in journals especially devoted to women's and gender history, and through the workings of the International Federation for Research in Women's History. Such developments are promising for further research in global women's and gender history.

The very character of gender as an analytical category makes it an excellent tool for world historians working at any period and in any society or region. Women's and gender history yields a wealth of new knowledge about the global past. There is a lot to gain by exploring this field of world history—and a lot to lose from not doing so.

Women's Emancipation Movements

Gender discrimination occurs everywhere, thus women's emancipation movements occur worldwide, but the struggles experienced and the potential solutions vary widely. Because of this, answers to gender inequities are best addressed by women working together within a culture to advocate for change that is acceptable to all. Gender may be universal, but there is no universal solution to gender inequality.

During the nineteenth and twentieth centuries, women's emancipation movements, whether they were called the "woman question," "women's rights," or "feminism," challenged the Western family economy in which the primary role of women is that of wife and mother, with waged work being a secondary role. Because people saw the domestic sphere as primary, women's work outside the home was undervalued and undercompensated. This distinction caused male domination of the political system with little hope of a reorientation of women's position in society. During the past two centuries women (and a number of men) worked to change this system politically, economically, and socially with varying degrees of success. They rarely took race and class into account, and people usually had an unacknowledged view of universalism toward women in other parts of the world. That is, the position of Euro-American feminists was that all women have the same oppression to overthrow and that common tactics will be useful in all circumstances.

Today students of women's lives recognize that geography is a factor. Although many feminists claim a universal theory of injustice and advocate a universal platform of change, their experience is limited to

industrialized and democratic nations. Areas of the world that have experienced long histories of colonization or that have operated under forms of socialist, collective political systems present radically different challenges to women and call for varying approaches to change. For these reasons the term *women's movements* (plural) is more appropriate for the twenty-first century. The plural (*movements*) acknowledges the validity of dissimilar approaches, and the plural (*women's*) rather than *woman* recognizes that not all women face the same issues in widely divergent geographical areas. The elimination of the word *rights* is a nod to those cultures that do not see adversarial positions as desirable in finding solutions. Women's movements reflect the different histories, cultures, and political systems of people who have a gender in common but perhaps little else.

Britain and the United States

During the nineteenth century, suffrage (the right to vote) received the most emphasis among women's rights groups, but many middle-class women also saw social reform as their defining characteristic. With the rapid urbanization caused by industrial changes, the middle class grew in influence; women asserted their participation by addressing the miseries caused by the new orientations of society and wished to influence legal reforms by exercising the vote.

In addition to working for suffrage and engaging in good works, women during the nineteenth century on both sides of the Atlantic Ocean were interested in the very nature of womanhood. They debated fiercely what makes women different than men, and they discussed what all women desire. They also assumed

Memorial service for a sati victim, held in a grove. Traditionalists and extremists in India clash over the practice of sati (immolation of widows on their husbands' funeral pyres). Photo by Klaus Klostermaier.

that women of all classes and races are the same and that gender alone is the overriding difference in social constructions.

Women's concerns were much the same in both countries with minor exceptions. Women in the United States tended to claim some moral superiority because the United States was more democratic and equitable than Britain, but British reformers tartly pointed to the existence of slavery in many U.S. states.

By 1924 both groups had achieved suffrage (although women under age thirty did not gain the vote in Britain until 1928), opened employment for many women, and amended the most oppressive marriage laws. At this point many feminist groups turned to public health issues, especially birth control and expanded legal rights for women. No single issue, however, emerged to unite all women as suffrage had. Women seemed to be disappointed with the goals achieved and confused about future goals.

Neither country was more radical or more effective. The major discouragements to women seemed to stem from the absence of change after women were granted the vote. The majority of women in both countries

seemingly were not won over to reformist or radical platforms in women's issues. Despite changes in the law, men did not accept women as political and economic equals. The biggest disappointments for women were in the inability of feminist groups to redress the inequalities in marriage.

The drawbacks inherent in legal changes were clear when the Equal Rights Amendment failed to pass in the United States in 1923 and again during the last quarter of the twentieth century. The unlimited optimism of the Victorian era was squelched by the inability to achieve equal rights in the legal arena.

Political Variations: Latin America

Although Latin America is close to the United States in geographical terms, the differences in political, racial, and economic structures have influenced the development of different sorts of feminist concerns. In Latin America women's movements cannot be separated from the context of military authoritarianism and the struggle toward political freedom.

Many people do not realize that women in Latin American nations have been active in political

As the twentieth century approached, women in the military were increasingly permitted to serve in offensive land operations. These three women, German machine gunners, were captured by American troops during World War I.

movements in the past, and often those people who study Latin American politics discount the interaction of women with politics, but it was historically important.

Feminist newspapers played an important role in disseminating ideas as long ago as the nineteenth century in Brazil. Since the mid-twentieth century urban life has provided a backdrop for networks of neighborhood women agitating for better services and lower consumer prices. Women participated in strikes and joined political parties even before they had right to vote, which came much later than in the United States or in Britain; Ecuador was the first Latin American nation to grant women's suffrage in 1929, although it did not possess a liberal democratic tradition, and Colombia was the last Latin American nation to grant women's suffrage in 1957. The suffrage movement in Latin America produced uninspiring results. As in the West, it was led mainly by middle-class women, and it aimed to produce reform rather than radical social changes. Women's suffrage did not cause a significant change in Latin American societies in part because women who did vote supported the status quo and were subservient to the politically conservative Catholic Church. No large-scale shift in attitudes occurred in part because no concerted effort took place to join economic and educational change for women with the right to vote.

Because suffrage came so late and because it failed to institute real change in women's lives in Latin America, few people would have predicted the emergence during the 1970s of women's movements that were important in destabilizing military regimes. In addition to agitating politically, women's human rights groups, feminist groups, and organizations of poor urban women began to cooperate.

In Argentina, for example, women who previously had never involved themselves in politics and did not define themselves as feminists stepped onto the political stage to protest the loss of their husbands and family members, known as "the Disappeared"—people whom military regimes regarded as enemies. The attention that the women's testimony received from the press around the world affected military rule.

Other feminist groups were formed by women from leftist parties who were frustrated by the failure of the left to take women's issues seriously. They agitated for women's issues as well as for the end of military dictatorships.

By the late 1980s the most striking aspects of the women's movements in Latin America were the contributions the movements made in overthrowing military dictatorships and in reconstructing civil society. By the end of the twentieth century this experience in cooperation led many people to concentrate on issues of class and race; poor women developed the organizational skills to combat sharp cutbacks in state spending, and women's demonstrations forced political leaders to change course.

Postcolonialism and Culture: South Asia

South Asia shows that social justice and equality in family life cannot be culture free. Unlike women's movements in Euro-America, women's movements in India and surrounding countries have to negotiate ardent nationalism, divergent religious practices, secularism, and polarized political views to present an agenda directed toward change in women's lives.

In addition to confronting a multilingual and multicaste society, reformers can appear to oppose

The history of men's opposition to women's emancipation is more interesting perhaps than the story of that emancipation itself. • **Virginia Woolf (1882–1941)**

ancient practices. The complexity of a postcolonial society includes the danger that a platform that advocates modernization can be construed as conflicting with tradition. Reform that advocates the equal rights of women can be manipulated into appearing to be linked with the views held by the former colonial power.

In addition to confronting suspicion of reform, advocates of women's rights in south Asia must confront the tensions among major religions that have sharply conflicting positions. For example, Hindu traditionalists have supported sati (immolation of widows on their husbands' funeral pyres) in the face of feminist opposition. In the same vein Sikh extremists have continued to deny inheritance rights to women, and Muslims have resisted the granting of maintenance to divorced wives. All groups are suspicious of efforts by women to initiate reform and tend to oppose any reform as an erosion of religious tradition and power.

South Asian feminists face many complexities beyond simple changes in policy. Before independence many feminists believed that an independent nation would naturally bring with it equal opportunities for women. The decades after independence have demonstrated that the situation is far more complex, not least because women do not always share the same goals. Whatever the goals, south Asian feminists must maintain a clear distinction between themselves and Western feminists. This distinction is the only way to deflect accusations of sympathies with a colonial and imperial past.

Stereotypes and Diversity: Africa

The colonial past also influences many aspects of the present in Africa, including the perceptions of African women. People in the West often perceive of African women as victims or as ignorant simpletons who cannot manage new technologies, as victims of oppression rather than as agents of change. No typical African woman exists, of course, and this simplistic perception of a whole continent of women is misleading and counterproductive.

The largest difference between African women and other women in the world is that African women are frequently the primary economic providers for their households as farmers and traders. This complicated power structure challenges Western understandings of marriage and households as partnerships in which men are the main providers, and household funds are pooled. When women challenge the web of social relationships, as in south Asia, opponents appeal to custom and tradition as against "colonial" influences.

The education of girls is often an issue between advocates of gender equality and the resident power structure in Africa. Schools both strengthen social values about femininity and reinforce domesticity in girls. For example, nutrition education programs focus on how meager resources can be used to greatest effect, but if girls were encouraged to understand the causes of food scarcity, they might challenge policy. African governments frequently point to great improvements in education for girls and women by publishing statistics reflecting a strong commitment in education. Interpreting data published by governments is problematic, however, because statistics are notoriously unreliable in the developing world. Statistics often create the illusion of precision and certainty, but that illusion serves political ends by projecting a positive image while obscuring political indifference.

Even those African girls who are well educated often are not able to translate schooling into self-determination. Professional women sometimes find that because of social influences, their husbands make most of the decisions that affect their lives. More education might mean less control over one's life. No single generalization is possible.

African women are usually portrayed as a powerless group subject to poverty and ignorance, in contrast to Western women, who are portrayed as educated, modern, and free to make their own choices. These portrayals often lead to programs that reinforce patriarchal ideology and inequalities. African women have access to programs that stress women's health and reproductive issues. These programs are useful, but

emphasis on such issues recognizes unequal power relations in the family but does not address ways to remove gender stereotypes.

People in Africa should address women's problems in a multifaceted way. Local women need support from grassroots movements as well as recognition from international groups. African women are rarely asked to help design programs and strategies because standards for evaluation are frequently projections of Western analyses and models. African women must be asked to project their own goals for their own futures; they should be allowed to trust their own insights as the basis for resolving issues of gender equality.

Socialism and State Power

International politics as well as historical events often affect attitudes toward women today. Countries that have undergone radical political change demonstrate the interaction of the personal and the political. The rapid disintegration of a socialist or Communist political system does not mirror a parallel change in gender relations.

In socialist societies the view of women reflects that of the German political philosopher Karl Marx and the German socialist Friedrich Engels; that is, the subordination of women is just another aspect of class oppression. Engels believed that with the abolition of private property and the integration of women into work, women would gain economic independence and equality. The flaw in this construction is that male control of female sexuality and inheritance predates the existence of the bourgeois family and industrialization. In reality, in socialist societies the male political leadership often had much the same view of the role of women as did their bourgeois counterparts.

The notion of a large socialist family was quickly established as a desirable goal, and so abortion was abolished in the Soviet Union in 1936. The state encouraged women to remain primarily responsible for child care as well as to accept employment in the public arena. This Soviet model of women's dual role was

quickly adopted as the basis of state policy in Eastern Europe, and the needs of the state took precedence over those of women. Because women were primarily responsible for activities in the private sphere, they frequently received blame for social problems such as juvenile crime and alcoholism, which were not addressed by the state.

Under the socialist system radical measures were implemented on maternity leave and child care, but they were not progressive because parenthood was seen as the exclusive purview of women. Because of their heavy domestic duties, women were increasingly displaced in labor and political arenas. When we see this from a gendered perspective, this is not true reform.

These gender stereotypes and inequalities remained in effect during the postrevolutionary period, but little attention is given to this area because the greatest attention is given to the economic reforms. Just as the socialist system influenced by Marx and Engels did not bring true equality for women, we have no reason to suppose that a free market economy and democratic elections will change male dominance and female subordination. No single women's movement has emerged in Eastern Europe or in the nations of the former Soviet Union. The millions of ethnically and regionally disparate women would be unlikely to identify with a single movement, and little assistance is offered by the rest of the world, which is focused on political and economic issues.

Culture and Change: China

China presents an interesting amalgam of the gendered views of the socialist state but with distinctive regional and social peculiarities. Traditionally people in China viewed women as having a passive role in society, and this view was further complicated by the term *feminist*. People viewed feminism as a Western concept, hence a bourgeois concept to be avoided. The first women's emancipation movement in China came about as a result of state-initiated policy. In 1949, with the establishment of the People's Republic of China, the new socialist

The extension of women's rights is the basic principle of all social progress. • **Virginia Woolf (1882–1941)**

Chinese government decided to prohibit such oppressive customs as the binding of women's feet and prostitution. The official policy was to advocate full women's employment. Women were given the rights to education, the vote, and full employment. Because jobs were assigned, however, women were frequently channeled into inferior or powerless positions. This fact was not recognized because women's rights were seen as having been achieved through the efforts of the state rather than through the efforts of women themselves.

As was the case in the former Soviet Union, the People's Republic of China shaped gender relationships to suit the interests of central policy. Although massive changes were introduced during the 1950s, during the Cultural Revolution (1966–1976) the use of oppositional terms such as *right–wrong*, *correct–incorrect*, and *socialist–bourgeois* served to outline what was acceptable. No organization of women working for change could exist because under the rule of the Cultural Revolution, women already had equality.

Despite legislation, a large gap remained between women's legal status and their social status. Gender issues affected power relations between women and men in that, as in the former Soviet nations, the idea that women are mainly responsible for standards of morality and family order was presented as "scientific fact." This idea that nature subjects women to lives dominated by reproductive concerns permeates Chinese approaches to education and employment. At the same time, the state is not a gender-neutral domain of power. More than any other Chinese state activity, the imposition of family planning that allowed only one child per family has been represented in the United States, especially during the Reagan-Bush era, as the quintessence of Communist oppression.

Recent movements toward privatization and a market economy have brought no improvement in women's autonomy in China. When privatization began in 1977, the idea that emancipation came not from individual efforts but rather from the state remained firmly in place. Further difficulties were introduced

with the dissolution of the planned economy; now women have more difficulty in getting jobs because competition favors men, and women must resign when they have a child.

The experiences of 1995's Fourth World Conference on Women held in Beijing provide a lesson in the cultural differences in women's movements. The Chinese women's movement that emerged from the Fourth World Conference is characterized by groups who are interested in promoting social change rather than depending on the Chinese state to improve the conditions of women. The groups and their tactics, however, are interesting reflections of the Chinese approach. No mass membership groups with demonstrations and organized displays exist as in the West, but rather the Chinese movement focuses more on service and voluntary work. Many people concentrate on scholarly work in women's studies centers at universities. Such groups are careful not to impinge upon state authority but instead to provide assistance to women or to increase knowledge. They concentrate on issues that are not addressed by the state. In this way the state recognizes that certain types of social movements are not a threat to its power.

The women's groups present issues of particular interest such as reproductive health, domestic violence, and sexual harassment as being global in nature. This presentation removes any critical tone that could be applied to the Chinese power structure, and so the power structure is more willing to tolerate steps to improve conditions in these areas. Work by women on reforms may be beneficial even to the state because the state is unwilling to pursue certain activities.

This peculiarly Chinese resolution of the dilemma of a women's movement provides a counterexample to the stereotype of a rigid, inflexible Chinese Communist regime. Chinese women are able to work toward reform and still appear cooperative rather than confrontational. The use of negotiation shows that gender attitudes and methods of reform are deeply rooted in culture and cannot be viewed as universal in nature.

Gender Past and Future

Women around the globe are divided by their histories, by their class or income levels, by the political basis of their nation, by their religious beliefs, and by their social expectations. The one fundamental similarity, however, in each culture is that gender provides a basis for discrimination and deprivation. We cannot prescribe one plan of action to improve the lot of women everywhere, but the recognition that gender is a crucial aspect in the consideration of political and economic reform is an essential beginning. Solutions to gender inequities are best constructed by women working together within a culture to negotiate change that is acceptable to the dominant power structure rather than presenting a universal program that may cause unintended results. Women's emancipation movements are global in scope because gender disparities occur everywhere, but the problems suffered and solutions undertaken vary widely. Gender may be universal, but no universal solution to gender inequities exists.

Women's Reproductive Rights Movements

The issue of women's reproductive rights came to the fore in the twentieth century. Early feminists demanded access to gynecological and contraceptive information; the movement later sought to give women the ability to control their own bodies and make decisions about contraceptives and pregnancy. Feminists and activists argue such rights will give women full participation, power, and status in society.

In 1968 the United Nations International Human Rights Conference overwhelmingly declared that reproductive rights should be acknowledged as basic human rights. This conclusion was based on the rationale that a woman's right to control her own body is an expression of free will. The reality is that for women in many countries, reproductive choice is in the hands of husbands or governments. What should be a woman's most private experience is in fact controlled and shaped by economic, political, and social institutions. Therefore, feminists around the world, irrespective of their ideological and political differences, are united in their desire to see women granted reproductive rights. It is an essential precondition for women's full participation in society.

What Are Reproductive Rights?

Reproductive rights comprise the right to decide timing and spacing of children, the right to access to gynecological and contraceptive information, the freedom to choose from different birth control methods, and the right to terminate a pregnancy if desired. It is an important feminist agenda because these rights are irrevocably entwined with women's

political, economic, and social status in society. In the United States and western Europe, where women are able to control their own fertility, they enjoy, relatively speaking, a higher status in society, whereas in some countries in the developing world, such as Bangladesh, Nepal, or the Central African Republic, where women are denied access to basic information, they are in a disadvantageous state economically, socially, and politically. Lack of information results in uninformed wives and mothers, increased instances of reproductive illnesses, and high maternal and infant mortality rates. Therefore, feminists are united in the view that women around the world should be able to control their own bodies and be granted the right to choose contraceptives and make informed choices about terminating a pregnancy.

Choice before the Twentieth Century

For centuries women across the globe have used vaginal pessaries, herbal douches, the rhythm method, extended breast-feeding, and herbal concoctions to control their fertility and limit births. In strictly patriarchal countries, where boys were preferred to girls, female infanticide was practiced to limit the female population or maintain a desired sex ratio. Trying to restrict fertility is not new; what is new is the concerted effort by feminists to grant women the right to control the decision of whether or not to have children as well as the frequency and number of children, as this has a great impact on their bodies and lives. Reproductive choice, feminists argue, should be in the hands of women and not husbands or governments.

It was in the midst of the momentous changes fostered by the Industrial Revolution of 1760s that

Birth Control Congress, Holland, 1910. Margaret Sanger's early advocacy of reproductive rights in America included her pamphlet *Dutch Methods of Birth Control* published in 1915. New York Public Library.

the idea of granting women reproductive rights first surfaced. As increased numbers of women were employed in factories, where pregnancy and childbirth would have an adverse effect on their employability, they turned to unreliable birth control and unsafe abortion methods in an effort to control their fertility. In the United States and Great Britain, the common perception was that abortion was not a crime until "quickening" (when the fetus begins moving). The Catholic Church at this time did not have a strong stand on the question of abortion.

In the 1870s, however, as the use of birth control and abortions grew, three groups—male medical practitioners, industrialists, and eugenicists—coalesced and called for outlawing abortion and establishing considerable male control over women's fertility. Male physicians wanted to monopolize women's health by encouraging the rapid medicalization of childbirth. This resulted in marginalizing female midwives.

Industrialists wanted to increase their productivity and profits by employing more women and children. Eugenicists argued for the rapid demographic growth of peoples of European descent at the expense of "others." The United States government responded with the Comstock Act of 1873, which restricted distribution of any material considered obscene; information on abortion and birth control came under the purview of this restrictive law. As a consequence, women were denied gynecological and contraceptive information.

From 1900 to the 1950s

The beginnings of the twentieth century coincided with the first battle for reproductive rights in the form of demands for access to gynecological and contraceptive information. U.S. activists such as Margaret Sanger (1879–1966) and the socialist Emma Goldman

Demonstrators protest the candidacy of anti-abortion advocate Ellen McCormack at the Democratic National Convention, New York City, 14 July 1976.

Photo by Warren K. Leffler, Library of Congress.

(1869–1940) and British activists such as Marie Stopes (1880–1938) held public forums to advocate that reproductive rights were crucial to improving women's status in society. They argued that working-class and poor women be allowed access to information. Despite being publicly ridiculed, harassed, and arrested under the Comstock Act, Sanger and Goldman successfully overturned it. Sanger founded the American Birth Control League, the forerunner of today's Planned Parenthood. In Great Britain, Marie Stopes continued to campaign for more government funding to open clinics that would provide women with information that would help them to make informed choices.

But efforts to open birth control clinics both in the United States and Europe met with considerable resistance from the government as well as the church, especially during the post–World War I years. A drastic

decline in birth rates prompted the United States and most European governments to attempt to control women's fertility by encouraging births. Women were rewarded for producing many children, and indeed, during the decades following World War I, women's fertility was linked to national vitality and prestige. Most European governments introduced comprehensive welfare programs to aid and encourage parenthood. At the same time, eugenicists lobbied hard to influence Western governments to control fertility by restricting the birthrate among groups deemed "socially inappropriate." Abortions and involuntary sterilizations were performed clandestinely, often in unsanitary conditions, on women belonging to these groups.

Abortion Rights

The 1960s were a major watershed in the reproductive rights movement. Women on both sides of the Atlantic discovered feminist theories linking reproductive and sexual freedom to improving the quality of their lives. They began to question their traditional roles as wives and mothers and articulated their need to control their own bodies in order to be liberated. The invention of the birth control pill (approved by the U.S. Food and Drug Administration in 1960) was a major step in that direction, as it allowed women the freedom to be sexually active without the fear of becoming pregnant, if they so chose.

In the United States, the women's movement of the 1960s linked reproductive rights to political, social, and economic power for women in society. Feminists demanded easy access to contraceptive and gynecological information. They also exposed the hazardous conditions under which illegal abortions were performed, primarily on the poor and women of color. They stated that abortions were conducted without anesthesia and frequently in unsanitary conditions that seriously jeopardized the health of the mother.

Therefore, by 1970, the abortion issue emerged as a central issue in the women's reproductive rights movement in the United States. While moderate

and liberal feminists argued for reforms in outdated abortion laws, the radicals wanted nothing less than repeal of all abortion laws and the lifting of the government's and the medical establishment's control over abortion. Their slogan was "the personal is political," and they vehemently argued that all women, irrespective of race, ethnicity, and class, should have the right to control their bodies and to choose to have an abortion.

The increased politicization of the abortion issue affected public opinion. By 1970 more and more Americans believed that abortion was a private matter and that a woman should have the right to decide what was best for her. In 1973, the U.S. Supreme Court's *Roe v. Wade* legislation granted a woman and her doctor the right to choose an abortion within the first three months of pregnancy. This was an important step toward legalizing abortion, although the right to abortion continues to be contested in the United States to this day.

Following the example of the United States, women activists across the globe are lobbying to legalize abortion. According to the United Nations, around 46 percent of women live in countries such as Germany, India, Argentina, and Saudi Arabia, where abortion is available only under certain circumstances, such as when the pregnancy was caused by incest or rape or when either the mother's health or fetal health is impaired. Around 38 percent of women live in countries such as South Africa, Norway, Holland or the former Eastern European countries, where abortion is available upon request. In other countries, such as Chile, Malta, and Andorra, abortion is strictly forbidden.

Common Birth Control Methods

Making informed choices about birth control is another crucial focus of the reproductive rights movement. Activists for women's reproductive rights argue that as it is the woman whose health is affected by pregnancy, a woman should be the one to make the decision regarding which birth control method to adopt. In many countries women's birth control options are not only limited, but governments,

Women in the Netherlands in the early 1970s had a novel option for storing (and being reminded to take) their birth control pills. The alarm pill box could be set to ring at 24-hour intervals, at which time a red light would flash and a drawer pop open; when the pill was removed a green light would come on and the drawer snap shut. Nationaal Archief, Netherlands.

pharmaceutical companies, and husbands often impose their views. Generally speaking, there are four birth control methods: barrier methods, hormonal methods, mechanical methods, and sterilization. The first method comprises diaphragms, condoms, and the cervical cap. These contraceptives provide effective means of preventing pregnancy, and the condom has the added benefit of protecting against sexually transmitted diseases. Hormonal methods consist of birth control pills, Norplant, and Depo-Provera. The interuterine device (IUD) is a mechanical method of birth control that is believed to work by preventing an egg from implanting in the uterine wall. There are also interuterine systems, which are essentially

IUDs that dispense the hormones that prevent pregnancy. Sterilization involves a procedure called tubal ligation, in which the fallopian tubes are tied, thereby preventing eggs and sperm from meeting, and, consequently, pregnancy. Many governments use tubal ligations to forcibly restrict population growth among certain groups.

Population Control Programs

Since the mid-1990s, the reproductive rights movement has focused on population control programs. Despite the existence of the U.N. Convention on the Elimination of All Forms of Discrimination Against Women (CEDAW), which admonishes governments against implementing aggressive population control programs to promote national interests, most countries in the developing world have such programs, often at the expense of women's health. Governments may be either pro-natalist or anti-natalist. Feminists are critical of both groups, as both restrict women's choices, though with opposite goals.

Pro-natalist governments want to increase their nations population; they typically outlaw abortion and contraception and seek to gain complete control over women's fertility. Prolonged warfare, loss in productivity, or even, in some instances, increasing numbers of people of racial, ethnic, or religious groups that the government considers undesirable have all been known to provoke a pro-natalist reaction. For example, in 1966 the former Romanian dictator Nicolae Ceausecu banned abortion and encouraged women to produce as many children as possible because he wanted to increase the national productivity.

Women activists also criticize anti-natalist governments that implement coercive and selective policies. Communist China's one-child policy to restrict population growth is an example of coercive anti-natalism. In such cases the government's desire to control population growth often comes at the expense of women's health. The United States was guilty of anti-natalism in the early 1950s and 1960s, when federal funds were used to perform forced sterilization on Chicano, black, Native American, and Puerto Rican women.

It is paradoxical that while women are responsible for producing the future generations, their right to control their own bodies is limited by public and private forces. Reproductive rights, with all their ramifications, are a reflection and determinant of women's equality in society.

In the nineteenth century, large numbers of women began to advocate for participation and legal protection in matters affecting their daily lives. By mid-century, this struggle had become increasingly political, and women's suffrage—the right to vote—became central in this movement. New Zealand was the first country to grant women suffrage in 1893.

Women around the world have fought for the right to vote (suffrage) for centuries. Women have sought to participate actively in political life and to have a voice in shaping the contours of their societies. By the 1990s the vast majority of women throughout the world had gained the right to vote in local and national elections, and in many countries they have achieved high office as elected politicians. As of early 2010, women still can't vote (but men can) in Saudi Arabia and the United Arab Emirates.

Background

During the nineteenth century, women in many parts of the world began working to achieve such personal liberties as the right to hold property and the right to divorce, with the goal being to obtain protection under the law and legal recourse in matters related to their daily lives. By the mid-nineteenth century, women's movements became increasingly political, and the centerpiece of the various movements was women's suffrage. From the latter part of the nineteenth century through the twentieth century women made great strides in obtaining human and political rights, including voting rights. New Zealand (1893),

Australia (1902), Finland (1906), Norway (1913), Great Britain (1918), Russia (1917), Germany (1919), and the United States (1920) were among the first nations to grant women the vote.

During the early years of the various women's movements, thousands of women marched through the streets making themselves heard, flooded the legislatures with petitions for the vote, and continually appealed to male politicians to support the female franchise. Historians, political scientists, and sociologists

Susan B. Anthony, co-founder with Elizabeth Cady Stanton of the American Equal Rights Association, an organization for white and black women and men dedicated to the goal of universal suffrage.

Elizabeth Cady Stanton was a major force in the First Women's Rights Convention at Seneca Falls, New York, in 1848.

have argued that cultural transformations brought about through rapid industrialization, war, and other social upheavals contributed to shifts in political participation and the shaping of a political identity for women globally. Some have argued that nations that have undergone restructuring due to decolonization or war have become more progressive, with the most democratic of these nations gradually implementing more egalitarian policies in government that recognize women's value as voters and political leaders.

Revolution and Suffrage

While over time women have been successful in gaining the vote, that right has been hard won. Although

women organized for broader gender rights, the majority of the leaders of women's rights movements from World War I through the postcolonial period realized the franchise was necessary if they were to have power and promote positive change. In 1945, in post-World War II Japan, about 67 percent of the newly enfranchised women voters turned out to vote, and by the 1970s *tatakau onnatachi* ("fighting women") were fighting against sexist laws, seeking wage equity, and establishing themselves as politically informed voters.

Women have often entered the suffrage arena through participating in national struggles for independence, as was the case for women in Egypt, Vietnam, and South Africa. In those countries, women and men worked together toward national independence, and in that context nationalism promoted women's suffrage and allowed for women's voting rights. For example in Egypt, the nationalists who worked toward building a modern nation-state independent of Great Britain saw improvements in women's restrictive lives as integral to their program. Feminist activists became the center of the anticolonial movement. Egyptian women began to push for women's rights, including the vote, in earnest after World War II, and liberal (male) nationalists supported the early efforts of women like Bahithat Al Badiya, who pushed a feminist political agenda that called for equality and opportunity for Egyptian women. By the 1950s, however, Islamic traditionalists were mounting resistance to women's suffrage, and some of the liberal nationalists made concessions to right-wing traditionalists. In spite of traditionalists' resistance, Egyptian women gained the vote in 1956, and during the same year a number of women became minor elected officials. In 1979, a presidential decree established that thirty seats in Egypt's parliament be reserved for women; the president also has the power to appoint a number of representatives, a proportion of whom must be women, to parliament. Unfortunately, an upsurge in Islamic fundamentalism has led to constitutional suppression of women's public and political space.

Suffrage Parade, New York City, 6 May 1912. Many suffragettes in the early twentieth century embraced the parade as a way of publicizing their cause; even negative media coverage helped spread the word.

In Vietnam, like Egypt, women supported anticolonial revolutionaries during the pre-World War II era, and their struggles eventually led to the defeat of French military forces in 1954, though it was more than twenty years before Vietnam, divided in 1954, was reunited under the Communists. In Communist Vietnam, socialist leadership paved the way for Vietnamese women's activism in political spaces. Women's newly formed public identities as warriors and liberators merged with their private identities as mothers and keepers of national heritage. Scholars have argued that social revolution has historically promoted change in class relations and in the relative power of the state. Histories of countries such as Vietnam, however, suggest that vast continuities between pre- and postrevolutionary societies remained intact. Although women were encouraged to participate in revolution, few have made use of their right to vote or hold political office after the reunification of the country in 1976. As Vietnamese nationalists gained power, they assumed traditional patriarchal power and dismissed women's revolutionary activities and political gains as part and parcel to the climate of national revolt; thus, as the generation of women who had participated in the revolution died out, so did women's hope for political rights.

In South Africa under apartheid, women have had to bear the burden of the double-edged sword of racism and sexism in gaining voting rights. White South African women won the vote in 1930, women of Asian or mixed ethnic extraction ("colored") gained the vote in 1984, and black South Africans did not receive the vote until 1994, after apartheid was dismantled. Through the 1950s blacks organized through the African National Congress (ANC), led by Nelson Mandela. Gertrude Shope, an ANC member and chair of one branch of the Federation of South African Women (FEDSAW), organized black women to fight for equality and voting rights. White political leaders acted quickly to suppress the ANC and other organizations; Mandela was imprisoned and Shope went into exile, where she became the secretary to the head of the ANC's Women's Section. During the 1970s resistance resurfaced; the numbers of protestors were larger and included women, who wanted to end the continuous oppression in their daily lives through the achieving of voting and political rights. In 1991, as apartheid was beginning to crumble, Shope was elected president of the ANC's Women's League. In South Africa's first free elections in 1994, approximately 25 percent of South Africa's legislative seats were won by women. Despite these gains, persistent poverty and social ills, most

Cautious, careful people, always casting about to preserve their reputation and social standing, never can bring about reform. • Susan Brownell Anthony (1820–1906)

notably the AIDS epidemic, continue to negatively impact the lives of South Africa's women.

Europe and North America

Women from Europe and North America have had fewer difficulties than women from other parts of the world in obtaining the franchise, for reasons that include more liberal political policies in Europe and North America, less restrictive religious traditions, and women's emergence into the public sphere as wage earners. Although American and British women have been considered leaders in worldwide women's suffrage, women's political participation in the United States is rather lackluster, with just 55 percent voting in primary elections in 1992 and women holding just

17 percent of U.S. legislative seats. Among European nations Germany has a good track record, having granted women the vote in 1919 and with just over 73 percent of women voting by 1990 and 28 percent of legislative seats held by women.

Outlook for Women's Political Activism

The goal of most feminists in liberal-minded countries is to encourage women around the globe to participate in the voting process, to increase the number of women political officeholders, to create and pass laws that protect women and children against violence, to make the public aware of gender oppression, and to further the mission of equality for all citizens. Given the dedication

An illustration from *Punch Magazine* in 1851 warns that bloomers will allow women to “walk into situations hitherto appropriated to the harder sex.”

The arrest of a suffragette in London, between 1910 and 1915. George Grantham Bain Collection, Library of Congress.

of women in even the harshest situations and the most repressive of societies to work toward those ends, we can expect further advances in the years to come.

World Blocs— First, Second, Third, and Fourth

The Cold War clearly divided the world into two blocs: the First World (the United States and western Europe) and the Second World (the USSR and its allies). By the mid-1950s, some of the nonaligned, developing nations were classified as in yet another bloc arbitrarily named the Third World. The Fourth World has become a label for the world's stateless and powerless indigenous peoples.

In March 1946 the former British prime minister Winston Churchill declared that an “iron curtain” had descended across Europe, from the Baltic to the Adriatic. The curtain had divided the former allies into two distinct blocs, Churchill said during a long speech in the United States, called the First and Second Worlds. The First World included states, notably the United States and the nations of western Europe, that pledged themselves to some version of partly regulated market capitalism and that would, in 1949, form the North Atlantic Treaty Organization (NATO), a military pact against the Second World.

The Second World rejected market capitalism for some version of socialist planning, and it generally worked in collusion with the largest socialist state, the Soviet Union. “Warsaw, Berlin, Prague, Vienna, Budapest, Belgrade, Bucharest and Sofia: all these famous cities and the populations around them,” Churchill told students at Westminster College in Missouri, “lie in what I must call the Soviet sphere, and all are subject, in one form or another, not only to Soviet influence but to a very high and in some cases increasing measure of control from Moscow” (Churchill 1945). In answer to the formation of NATO in 1949, the USSR created the Warsaw Pact in 1955, a military

agreement with Albania, Bulgaria, Czechoslovakia, East Germany, Hungary, Poland, and Romania.

The Cold War

The First and Second worlds openly fell out when U.S. president Harry Truman announced his support for anti-Communist forces in Turkey and Greece (1946), when the CIA helped the Conservatives defeat the popular Communists in the Italian and French elections of 1947, when the Soviet Union forced the hand of the Eastern European states into its orbit, and when the animosity attained dramatic proportions during the Second World's blockade of Berlin beginning in June 1948. In this melee, Bernard Baruch, an adviser to Truman, used the term *Cold War* to describe the conflict, and the columnist Walter Lippman made the term widely known. The Cold War defines how most people see the period from 1946 to the fall of the Soviet Union in 1991: the East-West conflict, intensified by nuclear weapons, dominated the stage for this crucial fifty-year period.

The phrase *East-West conflict* distorts the history of the Cold War, however, because it makes it seem as if the First and Second Worlds confronted each other in a condition of equality. In an insightful article from 1968, the Swedish sociologist Göran Therborn described the Cold War as an unequal conflict that both sides presented and experienced as being equal. The Soviet Union and the United States portrayed each other as equivalent adversaries, although the former had an economic base that was far inferior to the latter. Despite the great advances of the Soviet regime in the development of the various republics, the Soviet Union began its

history with a battered feudal economy that was soon ravished by a civil war and then by the ferocious assaults of the Nazi war machine. In 1941 both the United States and the Soviet Union had populations of about 130 million, but whereas the United States lost upwards of 400,000 troops in the war, the Soviets lost between 20 and 30 million troops and civilians. World War II devastated the Soviet Union's economy, its population, and its capacity to rebuild itself. Furthermore, the imperatives of rapid development tarnished the ideals of Soviet society, with most internal freedoms being sacrificed in the building of its productive base.

The dominant classes in the First World used the shortages and repression in the Soviet Union as an instructive tool to wield over the heads of their own working classes, and so on both economic and political grounds the First World had advantages over the Second. Therborn further argued that an unequal conflict that is fought as equal, such as the Cold War, only redoubles the inequality.

The Third World

But the First and Second Worlds only accounted for about a third of the planet's people. What of the two-thirds that remained outside the East-West circles? By the mid-1950s, most of the planet that had been held in one way or another by colonial powers had gained or were struggling to gain their independence. These new nations defined themselves outside the Cold War division. In 1952 a French demographer, Albert Sauvy, coined the term *Third World* to refer to this bloc of nations. He explicitly used the term to evoke the French Revolution, an important inspiration for the decolonization process. Prior to 1789, the French monarchy divided its counselors into the First Estate (clergy) and the Second Estate (aristocracy), with a Third Estate being for the bourgeoisie. During the tumult of the revolution, the Third Estate fashioned itself as the National Assembly and invited the totality of the population to be sovereign over it. In the same way, Sauvy was suggesting, the Third World would

speak its mind, find the ground for unity, and take its place in the dynamic of world affairs. This was the enlightened promise of the Third World.

At Bandung, Indonesia, in 1955, twenty-nine of these Third World nations gathered to constitute an alternative to the Cold War's bipolar divisions. They demanded a world of peaceful coexistence, free of colonialism and injustice, in which economic cooperation and development topped the agenda, and in which political and cultural freedom had a priority over the rights of corporations. The Bandung conference, for all its divisions between pro- and anti-Communist delegates, provided a distinct voice in world affairs, one that refused to accede to the terrors of the Cold War and the demands of one or the other superpower. The Third World rejected the term *neutralist* because it smacked of renunciation; they favored terms such as *nonaligned* to indicate that they supported dialogue and debate without the threat of war as a means to enable the planet to redeem the promises of modernity.

The Third World's efforts nurtured and one might even say *produced* the United Nations. At the U.N.'s founding conference in San Francisco (1945), the Latin American delegates insisted upon a comprehensive section on human rights for the charter. They fought hard to get statements on education, work, health care, and social security. In London, some months later, at the founding conference of the United Nations Education, Scientific

and Cultural Organization (UNESCO), the Third World delegates, led by India and the Arab nations, successfully fought to have the organization forge a strong social-justice agenda. Within the U.N., the Afro-Asian-Arab (and later Latin American) group offered an important measure of balance in the General Assembly in debates on international security and the crises of the Cold War. In forums such as the U.N., at Bandung, and in the nonaligned conferences (from 1961 onward), the Third World constantly stressed the importance of nuclear disarmament. The Third World nations understood that the nuclear bias within the Security Council meant that the U.N. had an institutional bias against nuclear disarmament, which is why they fought to revise the membership rules for the Security Council (and its veto system). Finally, it was pressure from the Third World through its Group of 77 that provided the United Nations with an agenda for social and economic development (the U.N. Conference on Trade and Development), for a critique of transnational corporations (the U.N. Center for Transnational Corporations), for international policy on food insecurity (the Food and Agricultural Organization), and for other such matters. The Third World pushed on these lines and helped to forge the multilateral institutions that are so much a part of our modern world.

Like the First and Second Worlds, the Third World was not so much a geographical entity as a political

one. To use the term *Third World* to refer to poverty and corruption is a distortion of the emergence of the term among the anticolonial and anti-imperialist forces of the 1950s and the 1960s. That the Third World agenda did not succeed has as much to do with the recalcitrance of the first two worlds and the unequal international finance system that favored the former colonial powers (mainly in the First World) as it does with the various internal problems of the countries that saw themselves as part of the Third World. A lack of investment funds, a lack of land reform, a lack of institutional probity, a failure to deal with internal power dynamics—all these were factors in the demise of the political project of the Third World. As the Third World began to founder in the 1970s, many of its countries welcomed investment funds from international lending agencies such as the International Monetary Fund and the World Bank. These changes

led to the end of the state-centered development and rights agenda of the Third World.

The Fourth World

In the 1950s, before the Third World ideals collapsed, partisans of those who did not stand to benefit from its agenda had already begun to speak of a Fourth World. In 1957 a Catholic priest, Joseph Wrensinski, convened a gathering in Paris entitled *Aide à Toute Détresse* (Aid to All Distress), or ATD. Like Sauvy, Wrensinski drew from the French Revolution, whose Fourth Estate, outside the government system, represented all those who languished in poverty. For Wrensinski and the ATD Fourth World movement that he created, the Fourth World represented those without power and means who lived in all parts of the planet. In 1974 Chief George Manuel of the Shuswap peoples in British Columbia, Canada, wrote an important book entitled *The Fourth World*, in which he defined the Fourth World as the indigenous peoples of the world, who no longer had the rights to their own lands and those lands' riches. Manuel's 12 million indigenous people around the world overlapped with, but were not identical to, Wrensinski's international impoverished. Manuel added the crucial dynamic of aboriginality to the discussion to ensure that the millions who had been overrun by colonialism and by nationalism would not be lost in the planning process for modernity.

Subcomandante Marcos of the Zapatista Army for National Liberation (EZLN), active in the impoverished state of Chiapas in Mexico, uses the term "Fourth World War" to describe the condition of the Fourth World. The Third World War was the Cold War, which lasted from 1946 to 1990. After that, Marcos argues, there were no checks on neoliberalism's appropriation of all the resources around the planet that had been held in trust as public goods or else by indigenous peoples in reserved areas. With the fall of Communism, neoliberal forces want to open up every resource to profit. This Fourth World War is not a war between nations, but a war of corporations against people.

“For neoliberalism,” Marcos said in a 1999 speech, “everything is merchandise, it is sold, it is exploited. And these indigenous come along and say no, that the land is mother, it is the repository of the culture, and that history lives there, and the dead live there. Absolutely absurd things that cannot be entered on any computer and which are not listed on a stock exchange. And there is no way to convince them to go back to being good, to learn to think properly. They just don’t want to. They even rose up in arms” (Marcos 2003). The EZLN uprising in Chiapas in 1994, as the North American Free Trade Agreement came into effect, provided the first major salvo against the suppression of the Fourth World. But it is not alone. North of Chiapas, at Cancún, when the international community met in 2003 to define the international trade rules, they had to deal with twelve former Third World nations (the G-12) led by Egypt, India, Brazil, and South Africa, who wanted a more equitable system, one that would be favorable not only to the former Third World, but also to the Fourth World within.

Since the Four Worlds’ framework is a political theory, the definitions are political and contested, and its future cannot be left to the cold calculations of analysis. We shall have to see if the Fourth World develops any traction, if the Third World reemerges, if the First World is able to hold its fragile alliance

together. The Second World has disappeared, but it too may reappear in another guise.

World History, Writing of

World history is one of the oldest, most persistent, and most pliable forms of history writing. It can best be characterized by multiplicity: in the use of data from different times and places; in the blending of methods from a broad range of disciplines; in the diverse backgrounds, assumptions, and world orders of authors; and in the mixture of narrative styles and organizational concepts.

No simple methodological definition of *world history* is possible, for world histories vary widely in style, structure, and scope. Furthermore, a wide assortment of labels have been used to describe them, including “universal history,” “ecumenical history,” “regional history,” “comparative history,” “world systems history,” “macrohistory,” “transnational history,” “big history,” and the “new world” and “new global” histories. Despite terminological differences, however, world histories share the purpose of offering a construction of and thus a guide to a meaningful “world”—a “realm or domain *taken for* an entire meaningful system of existence or activity”—by historians or people in the past (Hughes-Warrington 2004, 4). Thus in this sense *all* histories are world histories. Where histories differ is in the degree to which the purpose of world construction is explicit.

Origins and Ancient Universal Histories

Herodotus (c. 484–430/420 BCE), commonly described as the “father of history,” is also credited for recognizing that history can be a means for understanding the world. In his *Histories*, Herodotus

delimited the military and political history of the Greeks in part by discrimination from barbarian “others,” and thus established the link between world history writing and actual and desired world orders. Studies of the field typically begin at a later point, however, with the emergence of the genre of “universal history.” “Universal history” has at least four meanings. It denotes, first, a comprehensive and perhaps also unified history of the known world or universe; second, a history that illuminates truths, ideals, or principles that are thought to belong to the whole world; third, a history of the world unified by the workings of a single mind; and fourth, a history of the world that has passed down through an unbroken line of transmission.

Universal history is conventionally thought to have emerged with the Greek writer Ephorus (405–330 BCE) and the climate of cosmopolitanism engendered by the conquests of Alexander of Macedon (Alexander the Great, 356–323 BCE). Raoul Mortley (1996) has also tried to demonstrate the influence of Aristotelian philosophy on the emergence of the genre, but the survival of less than 5 percent of Hellenistic literature makes the formulation of general explanations difficult. Additionally, it is not always clear whether extant histories might have been parts of universal histories: for example, commentators have argued that the *Anabasis Alexandri* and *Indica* of the Roman historian Arrian (c. 92–c. 180 CE) were originally united. Even José Miguel Alonso-Núñez’s more inclusive description of the first universal historians as those who dealt “with the history of mankind from the earliest times, and in all parts of the world known to them” is problematic, because it masks the contribution of those—particularly women—who

Heinrich Leutemann, *Herodotus Reading His History to the Assembled Greeks* (c. 1885). Herodotus, the fifth-century BCE Greek historian, established a methodology for writing history that is still recognized today.

composed biographical catalogues (Alonso-Núñez 1990, 197). While not exhaustive in time or space, biographical catalogues were designed to illuminate universal social, moral, or political principles.

Any history of the field must also take into account the rich tradition of Chinese and Islamic universal history writing, which dates from at least the third century BCE and the ninth century CE respectively. It is likely, too, that the genre of universal history has a relationship with both oral and written creation or initiation stories told by peoples around the world since the foraging era. Universal history, and consequently world history, are thus not simply Western documentary forms bestowed upon the world through diffusion.

Ancient universal history writing flourished after campaigns of political expansion, the advent of

standardized systems of chronology, and the spread of monotheistic religions such as Christianity and Islam. Writers followed no single template, and their works varied widely in scope, structure, and world vision. A particular view of universal history might be adopted for a host of reasons, both intellectual and pragmatic. Polybius (c. 203–120 BCE) and Diodorus of Sicily (c. 90–21 BCE), for instance, agreed that the truth of history was to be gleaned by treating it as a connected whole, but whereas Polybius's decision was based on an observation of the spread of Roman power, Diodorus assumed the existence of a universal human nature.

Variations were also evident across cultural and religious groups. For example, as viewed by Eusebius of Caesarea (c. 263–339 CE), St. Augustine of Hippo (354–430), Paulus Orosius (fl. 414–417), and Bishop Otto of Freising (c. 1111–1158), God's work in the world and the victory of Christianity were to be narrated through a seven-age framework that had been adapted from Jewish works like Josephus ben Matthias's *Jewish Antiquities* (93 CE). Islamic writers like Abu Ja'far al-Tabari (c. 839–923) also saw universal history as structured through successive ages, though more commonly three than seven, and infused their accounts of events with predictions of future judgment. Furthermore, these accounts derived their status as universal histories in part because of their construction out of *isnads*: unbroken chains of transmission. For many Islamic writers of the Abbasid dynasty (749/750–1258), universal history thus entailed both chronological and historiographical continuity. Exceptions like Abu Al-husayn 'ali ibn Al-husayn Al Mas'udi's (c. 888–957) chronologically, philosophically, and geographically arranged *Muruj adh-dhahab wa ma'adin al-jawahir* (The Meadows of Gold and Mines of Gems) were given a highly critical reception. Later writers eschewed *isnads* as a narrative and methodological intrusion and built upon Al Mas'udi's approach. Ibn Khaldun (1332–1406), for instance, combined philosophy, geography, and social theory in his *Kitab al-'Ibar*.

Chronologically arranged universal histories were also produced in China, as Sima Guang's (1019–1086)

Page from the *Hanshu* (History of the Former Han Dynasty), by Ban Gu (32–92 CE).

Zi Zhi Tong Jian (Comprehensive Mirror to Aid in Government) attests. But it is the synchronic, encyclopedic structure of official Chinese histories that most sets them apart from other historiographical traditions. A four-part division of histories into imperial annals (*benji*), tables (*biao*), treatises (*shu*), and biographies or memoirs (*juan* or *liezhuan*) was established by the first four official histories—the *Shiji* (*Records of the Grand Historian*) begun by Sima Tan (d. c. 110 BCE) and completed by Sima Qian (145–80 BCE); the *Hanshu* (History of the Former Han Dynasty) by Ban Gu (32–92 CE); the *Sanguozhi* (History of the Three Kingdoms) by Chen Shou (d. 297 CE); and the *Hou Hanshu* (History of the Later Han) by Fan Ye (398–445 CE). The first part of each work documented major events in imperial families; the second, month-to-month events for government offices; the third, knowledge concerning an enormous range of activities; and the fourth, accounts of virtuous and infamous individuals and collective biographies. Though modified, this structure was employed

in official histories right up to *Qingshi gao* (Draft History of the Qing Dynasty, 1928).

Interactions, Exchange, and Universal History

The growth of intellectual, economic, and socio-political networks of exchange in the foraging and agrarian eras prompted the defense, augmentation, and revision of universal and later world historical views. Labels and typologies were used to bestow respect upon, to accommodate, or subjugate newly encountered peoples. In many European universal histories, for instance, race and gender typologies coalesced in narratives of the stagnation of the effeminate East and the progressive perfection of the masculine West. Some writers used other cultures to make criticisms about their own: to take one example, Voltaire (1694–1778) used the history of China in *Essai sur les mœurs et l'esprit des nations* (An Essay on Universal History) to highlight the savagery, superstition, and irrationality of Christian Europe. Corresponding examples from outside Europe may also be found, like Wei Yuan (1794–1856), who compared the historical paths of Europe and China in *Haiguo Tuzhi* (Illustrated Treatise on the Sea Kingdom) based on the argument that learning the superior technology of the Europeans could be a means to control them. Universal histories were also used to promote the interests and ideals of particular social groups: for example, Philip Melancthon (1497–1560) and the bishop Jacques-Bénigne Bossuet (1627–1704) saw universal history as an excellent means to defend Christian beliefs. Promoting a different cause, in *The Book of the City of Ladies* (1405), Christine de Pizan narrated a hierarchical universal history of female warriors, good wives, and saintly women to empower female readers to aspire to the city of womanly virtue. Joseph Swetnam, on the other hand, argued in his pamphlet *The Arraignment of Lewd, Idle and Forward Women* (1615) that women are, like the rib that they were fashioned from in the Judeo-Christian creation story, “crooked by nature.”

Detail of a page from *The Book of the City of Ladies* (1405), by Christine de Pizan. Pizan intended her “city” of female warriors, good wives, and saintly women to empower medieval women and confront sexism and misogyny.

Universal histories proliferated after the aggregation of printing technologies in fifteenth-century Europe. This made decisions on the proper means of researching, writing, and reading them increasingly urgent to many writers. In *Method for the Easy Comprehension of History*, for example, Jean Bodin (1530–1596) advanced the notion that the logical order of universal history was chronological, from the general to the specific, and from Europe outward to the rest of the known world. “Mis-order,” in his view, could weaken the powers of the mind. Conversely, Christopher Cellarius (1638–1707) argued

for the tripartite division of history into “ancient,” “medieval,” and “new” periods.

The Philosophical Turn

Over the course of the seventeenth century more universal historians endeavored to establish a proper “scientific” or “philosophical” foundation for history. What these terms meant varied from place to place. In Scotland, for instance, “conjectural historians” such as Francis Hutcheson (1694–1746), Adam Smith (1723–1790), Adam Ferguson (1723–1815),

William H. McNeill holds the manuscript for *The Rise of the West* (1963) before submitting it to University of Chicago Press in 1962. McNeill is often regarded as a father figure in twentieth-century world historical studies.

John Millar (1735–1801), William Robertson (1721–1793), Dugald Stewart (1753–1828), and David Hume (1711–1776), worked to explain the origin of human sociability, a “moral sense” that would account not only for human community but also for human progress. The Italian scholar Giambattista Vico (1668–1744), on the other hand, saw the Latin language, Roman law, and the Homeric poems as a point of entry into the “scientific” study of the course and recourse of nations’ histories. French historians like Fontenelle (1657–1757), Étienne Bonnot de Condillac (1715–1780), the Marquis de Condorcet (1743–1794), Anne-Robert-Jacques de Turgot (1727–1781), and Jean Étienne Montucla (1725–1799) tracked the history of the “human spirit” or mind from barbaric beginnings to the height of enlightened, mannered “civilization.” In Germany, Johann Gottfried von

Herder (1744–1803) adopted an organic view, outlining the unique features of cultures in childhood, infancy, manhood, and old age. Immanuel Kant (1724–1804) detected reason in the long history of humanity’s “unsocial sociability,” Leopold von Ranke (1795–1886) sought the “holy hieroglyph” or mark of God and meaning in world cultures, and Georg Wilhelm Friedrich Hegel (1770–1831) detected “progress of the consciousness of freedom” in the movement of world history from the East to the West (*Philosophy of History* 1956, 19). Later in the nineteenth century, Karl Marx (1818–1883) inverted Hegel’s philosophical program, suggesting that the material conditions of life shape human freedom, not the other way around. Chinese historians, too, including Guo Songtao (1818–1891), Xue Fucheng (1838–1894), Wang Tao (1828–1890), Yan Fu (1854–1921), and Liang Qichao (1873–1929), increasingly urged the recognition of world history as a narrative of struggle for technological supremacy.

The Rise of Mass Literacy

Universal histories designed for mass consumption were also produced. Reader, reviewer, and publisher demands for morally edifying works favored the production of overtly didactic texts, often in the form of biographical catalogues. This type of writing proved particularly popular with middle-class women, who were given access to works designed to describe a world order in which women were the domestic companions of men. Notable examples include Mary Hay’s *Female Biography, or Memoirs of Illustrious and Celebrated Women, of all Ages and Countries* (1803); Lucy Aikin’s *Epistles on Women, Exemplifying Their Character and Condition in Various Ages and Nations with Miscellaneous Poems* (1810); Anna Jameson’s *Memoirs of Celebrated Female Sovereigns* (1832); Laure Junot’s *Memoirs of Celebrated Women* (1834); Mary Elizabeth Hewitt’s *Heroines of History* (1852); Sarah Josepha Hale’s *Woman’s Record* (1853); Mary Cowden Clarke’s *World-Noted Women* (1858); Sarah Strickley Ellis’s *The Mothers of Great Men* (1859); and Clara Balfour’s *Women Worth Emulating*

The only good is knowledge, and the only evil is ignorance. • Herodotus (484?–430/420 BCE)

(1877). While often dismissed as methodologically impoverished, many of these works acted as conduits for womanist and reformist thought. Lydia Maria Child's *The History of the Condition of Women, in Various Ages and Nations* (1835), for example, is underpinned by arguments against slavery and for female suffrage.

A Proto–World History?

From the eighteenth century, existing ideas about universal history came to be seen as increasingly out of step with the specialized national research that accompanied the professionalization of history teaching, research, and writing. Some accommodation was achieved through the production of multi-author, multivolume universal history compendia or encyclopedias, but this in turn spurred H. G. Wells (1866–1946) to define universal history in part by the “unity of presentation attainable only when the whole subject has been passed through one single mind” (Wells 1920, 2). It is assumed by many historiographical commentators that Wells's efforts were akin to Canute's attempt to defy the tide. In their view, universal history was a proto–world history that was ushered aside in the twentieth century as speculation was replaced by rigorous forms of analysis and a greater respect for primary evidence. Universal history, however, survives in many forms, such as philosophies of history (e.g., Raymond Aron, *The Dawn of Universal History*, 1961, and Daniel Dennett, *Freedom Evolves*, 2002); compendia (UNESCO's *History of Humankind*, 1963); the fusion of science and history in the subfield of “big” history (Fred Spier, *The Structure of Big History*, 1996, and David Christian, *Maps of Time*, 2004); and, of course, encyclopedias such as this.

Universal history did not disappear in the twentieth century; it simply became one of a number of approaches to the writing of what was increasingly called “world history.” Roughly contemporary with Wells's *Outline of History* were Oswald Spengler's *The Decline of the West* (1918–1922); Sigmund Freud's *Civilization and Its Discontents*

(1930); Arnold J. Toynbee's *A Study of History* (1932–1961); Jawaharlal Nehru's *Glimpses of World History* (1934); Lewis Mumford's *Technics and Civilization* (1934); V. Gordon Childe's *Man Makes Himself* (1936); Pitirim A. Sorokin's *Social and Cultural Dynamics* (1937); Norbert Elias's *The Civilizing Process* (1939); José Karl Polanyi's *The Great Transformation* (1944); Mary Ritter Beard's *Woman as Force in History* (1946); Karl Jaspers's *The Origin and Goal of History* (1947); José Ortega y Gasset's *An Interpretation of Universal History* (1949); and Christopher Dawson's *The Dynamics of World History* (1956). Though they present a wide range of foci—psychological, religious, political, philosophical, sociological, cultural, archaeological, and technological—a common interest in the trajectories of civilizations spans these works. In Spengler's view, for example, Western civilization was “Faustian” because the limitless ambition of its people was likely to be its downfall; similarly, when Toynbee began *A Study of History*, he detected a number of suicidal tendencies in Western civilization. During the composition of volume six of twelve, however, he modified his view and concluded that the future would bring an age of universal churches or of selflessness or compassion.

Modernization, Dependency, and World-System Analyses

A more optimistic assessment of “modern” or “Western” civilization was also offered in the works of modernization scholars, who showed particular interest in the historical paths of development in the West that might be used to study and foster development in the “developing” world. Key contributions to modernization analysis included W. W. Rostow's *How It All Began: Origins of the Modern Economy* (1975); Cyril Black's *The Dynamics of Modernization: A Study in Comparative History* (1966); Reinhard Bendix's *Nation-Building and Citizenship* (1977); and E. L. Jones's *The European Miracle: Environments, Economies, and Geopolitics in the History of Europe and Asia* (1986).

A disparate group of neo-Marxist scholars disagreed, noting the inability of modernization scholars to explain Latin American economic development, and suggested an alternative in the form of dependency and, later, world-system theory. While modernization scholars looked to the internal characteristics of particular civilizations, dependency and world-system theorists stressed the need to study networks of economic and political exchange, and more particularly inequalities in the distribution of roles, functions, and power that fostered states of dependency. Dependency theory was advanced first in the writings of Latin American scholars like Paul Baran (*The Political Economy of Growth*, 1957) and then taken to a global audience in Andre Gunder Frank's *World Accumulation, 1492–1789* (1978) and *Dependent Accumulation and Underdevelopment* (1979). Frank's work, in turn, influenced Immanuel Wallerstein, who went on to elaborate world-system theory in a series of works including the three-volume *The Modern World System* (1974–1989) and *Historical Capitalism* (1983). In *The Modern World System*, he argued that the system of the title originated in fifteenth-century Europe, was composed of a “core” (advanced industrial states), a “periphery” (weak states engaged in raw materials production), and a “semi-periphery” (intermediate states).

World-system analysis was combined with a range of methodologies, including anthropology (Eric Wolf, *Europe and the People without History*, 1982); archaeology (N. Kardulias [editor], *World-Systems Theory in Practice: Leadership, Production, and Exchange*, 1999); geography (Paul Knox and Peter Taylor, *World Cities in a World-System*, 1995); and cultural history (John Obert Voll, “Islam as a Special World-System”, *Journal of World History*, 1994). The range and scope of world-system studies also increased, with Leften Stavrianos (*Global Rift*, 1981), Janet Abu-Lughod (*After European Hegemony*, 1989), Frank (*ReOrient*, 1997), Frank and Barry Gills (*The World System: Five Hundred Years or Five Thousand?*, 1993), and Christopher Chase-Dunn and Thomas Hall (*Core/Periphery Relations in Precapitalist Worlds*, 1991) exploring

Afro-Eurasian systems of exchange up to seven thousand years ago.

The Relational Shift

Postcolonial scholars also adapted dependency and world system theory. First brought to the attention of world historians with the publication of Edward Said's *Orientalism* (1978), postcolonial theorists enhanced political and economic criticisms of colonialism with cultural analyses. Representation and language are crucial for the construction of an “other”: for example, Marshall Hodgson (*Rethinking World History*, 1993), Dipesh Chakrabarty (*Provincializing Europe*, 2000), and Ranajit Guha (*History at the Limit of World-History*, 2003) argued that the language, concepts, periodization, and structure of world histories can minimize and even mask the historical activities of those “outside” the West. World historians with an interest in postcolonial themes, such as Michael Adas (*Islamic and European Expansion*, 1993) and Margaret Strobel (*Gender, Sex, and Empire*, 1993), sought to balance the demands of aligning the experiences of colonized subjects and recognizing the specificities of race, class, nationality, religion, sexuality, epistemic, social, political, and economic hierarchies, and gender relations.

Dependency, world-system, and postcolonial world histories formed part of a wider shift in the twentieth century toward the study of relations between peoples across the globe. This shift is clearly discernable over the long career of William H. McNeill, often taken as a central or “father” figure in twentieth-century world historical studies. While the theme of diffusion shaped his first major world historical work—*The Rise of the West* (1963)—the depth and breadth of his interest in world historical webs of interaction emerged more fully in *Plagues and Peoples* (1976), *The Pursuit of Power* (1982), *Keeping Together in Time* (1990), and *The Human Web* (2003, with J. R. McNeill). Human interaction on the largest scale—over the globe—was also the subject of new global historical studies. New global historians like Bruce Mazlish and Ralph Buultjens (*Conceptualizing Global*

History, 1993), Anthony Hopkins (*Globalization in World History*, 2001), Roland Robertson (*Globalization*, 1992), Manuel Castells (*The Information Age*, 1996–1998), and Arjun Appadurai (*Modernity at Large*, 1996) looked to economic, anthropological, political, and cultural evidence to track the phenomenon of globalization—the emergence of an integrated anthropogenic globe—over the course of the twentieth century.

Transnational, comparative, new imperial, and new world historians were also interested in human interaction, but their works were smaller in spatial and temporal focus than those of other world historians. This contraction may be explained by reference to, among other factors, the perception that the recent explosion in evidence made large-scale synthesis too demanding, and postmodern and postcolonial claims that large-scale narratives were instruments of intellectual imperialism. Of particular interest to these writers were phenomena such as intergovernmental organizations, internationalist movements, technological exchange and diffusion, migration and diasporas, cultural hybridity, and transnational corporations. For example, trade and cultural diasporas centered on the Mediterranean, Indian, Atlantic, and Pacific Oceans were analyzed by Fernand Braudel (*The Mediterranean and the Mediterranean World in the Era of Philip II*, 1949); Philip Curtin (*The Atlantic Slave Trade*, 1969; *The Rise and Fall of the Plantation Complex*, 1990; *Cross-Cultural Trade in World History*, 1984); Niels Steensgard (*The Asian Trade Revolution of the Seventeenth Century*, 1974); K. N. Chaudhuri (*Trade and Civilisation in the Indian Ocean*, 1985; and *Asia before Europe*, 1990); Eric Jones, Lionel Frost, and Colin White (*Coming Full Circle*, 1993); John Thornton (*Africa and Africans in the Making of the Atlantic World, 1400–1680*, 1992); and Adam McKeown (*Chinese Migrant Networks*, 2001).

Widening Views of World History

Relations of power were also of central concern to world historians studying both women and gender. Gender history is not women's history, but rather the

study of varying relations between constructed gender categories. For example, Michel Foucault noted the shifting shape of "sexuality" across ancient and modern history (*The History of Sexuality*, 1976–1984), and Ida Blom has demonstrated how varying gender systems shaped understandings of the nation-state ("World History as Gender History," in Dunn 2000, 446–61). More recently, Marilyn Morris ("Sexing the Survey," *World History Bulletin*, 1998), Merry Weisner-Hanks (*Gender in History*, 2001), and Judith Zinsser ("Gender," in Hughes-Warrington 2004, 189–214) have drawn attention to the gender of world history writing, and argued that favored concepts, narrative forms, and even periodization frameworks have served to render the experiences of many women and men invisible.

In the second half of the twentieth century, world histories took an increasing interest in the ways in which the organic and inorganic environment have both shaped and been shaped by human activities. Jared Diamond, for instance, looked to the role of environmental factors in the emergence of the divide between the "developing" and "developed" worlds (*Guns, Germs and Steel*, 1998), and Brian Fagan considered the role of climatic phenomena like El Niño in shaping historical events (*Floods, Famines and Empires*, 2001). In contrast, Mike Davis stressed the opportunistic use of El Niño by colonial powers to create a world market economy (*Late Victorian Holo-causts*, 2001), and John R. McNeill outlined growing awareness of the impact of human activities on the Earth, from the pedosphere (the Earth's continental crust, rocks, and soil) to the stratosphere (*Something New Under the Sun*, 2000). Other writers have drawn upon conceptual models and theories from the natural sciences to explain historical changes: for example, in *Nonzero* (2000), Robert Wright looked to game theory; Stephen J. Gould (*Wonderful Life*, 1989) and Murray Gell Mann (*The Quark and the Jaguar*, 1994) disagreed about whether evolution implied increasing complexity; and Eric Chaisson tracked increasing energy flows from the big bang to the evolution of humans (*Cosmic Evolution*, 2000). More radically, too, writers like Dorion Sagan and Lynn Margulis

(*Microcosmos*, 1986) even questioned the privileging of human actions and argued for a world history centered on cells.

World History: Professional and Popular

While the twentieth century saw the emergence of organizations, journals, conferences, Internet discussion forums, and syllabi focused on world history, the field was not and likely will never be of interest to trained specialists alone. John M. Roberts (*The New Penguin History of the World*, 2003) and Mark Kurlansky (*Salt: A World History*, 2002) are just two of the many writers who have produced world historical works for the benefit of nonspecialist readers around the world. World history is and likely will continue to be characterized by multiplicity: first, in the use of data from different times and places; second, in the blending of many methods from a broad range of disciplines; third, in the diverse backgrounds, assumptions, and world orders of authors; and finally, in the mixture of narrative styles and organizational concepts. For this reason, it makes sense to speak of “world histories” rather than of “world history.”

World War I

As the inevitable outcome of nineteenth-century imperialism, local wars, and rival power blocs in Europe, World War I had tremendous consequences. It transformed territorial boundaries in Europe and destroyed three great empires. Ideas about class privilege and gender discrimination began to change. Political ideology was radicalized through communism, fascism, and socialism, and the international war debt contributed to a dire postwar economic situation.

World War I (1914–1918) was the great climax of the age of competitive imperialism. The deepest causes of the war lay in the struggle between the major European powers for control over territories newly occupied by Europeans during the late nineteenth century, especially in Africa, Asia, and the Pacific. This tension also was linked to competition in armaments and a generalized sense of rivalry in industrial development. As the period of economic liberalization of the mid-nineteenth century receded, it was replaced by an age of competing tariff regimes. Rivalries produced a series of localized wars and diplomatic crises during the two decades before 1914. Some conflicts reflected global competition, such as the Fashoda Crisis (1898) in Sudan, the South African War (1899–1902), the Russo-Japanese War (1904–1906), the Moroccan crises (1905 and 1911), and the Italian invasion of Libya (1911). Some rivalries reflected long-standing tensions in southeastern Europe, such as the crisis over the Austrian annexation of Bosnia-Herzegovina (1908–1909). These tensions in turn solidified the rival power blocs into which Europe had been divided, with Russia, France, and Britain bound in one alliance system (the Entente)

and Germany, Austria-Hungary, and Italy in another (the Triple Alliance).

Certain destructive political and economic doctrines also seduced educated opinion. Social Darwinist and geopolitical theories, which asserted the inevitability of wars to control resources, helped reconcile many people to the idea of armed conflict. Political pressure groups and the new cheap newspapers asserted imperialist and militarist values. Domestic political tensions, worsened by rapid industrialization, especially inside Germany and Russia, also tempted reactionaries to see a short and successful war as a means of escape from reformist or revolutionary movements.

On the other hand, countervailing forces existed. Both liberal and socialist internationalists promoted notions of peace through free trade or working-class solidarity. Increasing economic interdependence between the major powers caused many people to believe that war was unlikely. Some people hoped that the two Hague Peace Conferences of 1899 and 1907 signaled that a new international order was in formation.

The descent into war itself had European origins. On 28 June 1914 Archduke Franz Ferdinand, heir to the Austro-Hungarian throne, was assassinated in Sarajevo, Bosnia, by Serbian nationalists. The Austro-Hungarian government decided to use the assassination as an opportunity to inflict a military punishment on Serbia, its rival in southeastern Europe. Promises of German support, even if the humiliation of Serbia involved risk of a wider war, were obtained. Austria-Hungary delivered an ultimatum to Serbia on 23 July, demanding drastic action against nationalist extremists. The Russian government, supporting

This graph shows the number of battle deaths in the thousands by nation during World War I. Many hoped that peacemaking efforts of the League of Nations would prevent future devastating casualties of war.

Serbia, acted with equal vigor and instituted orders for “the period preparatory to war” on 26 July. The Austro-Hungarians opened their military campaign against Serbia on 28 July. The sequence of diplomatic events that followed during the next week ensured the escalation of a local war (between Serbia and Austria-Hungary) into a continental war (between Germany and Austria-Hungary on the one hand, and Russia and France on the other) and then a world war (when Britain declared war on Germany). All sides made errors that snuffed out hopes for peace. The Germans, whose leaders wavered between eagerness for war and a preference for a negotiated settlement, failed to press the case for mediation upon their Austro-Hungarian allies. Similarly, the British and French failed to discourage the Russians from precipitate action, always giving a higher priority to the preservation of their alliance system. The Russians recklessly ordered general mobilization on 30 July. The Germans, gambling mistakenly on British neutrality, rushed to declarations of war against both Russia and France on 1 and 3 August and violated Belgian neutrality on 3 August. The British, stung by this violation and determined to maintain their alliances against their chief imperial and commercial rival, declared war on Germany on 4 August.

No Quick Victories

The first months of fighting were marked by rapid military movements. The first battles, however, failed to deliver quick victories to those taking the offensive. On the western front the German invasion of Belgium and France was halted at the Battle of the Marne in France in September 1914. On the eastern front the Russian invasion of East Prussia was halted at the Battle of Tannenberg in late August. After the first Battle of Ypres in Belgium in November, a vast line of trenches in the west stabilized. By this time the war had escalated globally. Japan entered the war on the Entente side in August in order to secure German possessions in the Pacific and China. Turkey entered on the side of the Central powers (Germany and Austria-Hungary) in November, hoping to profit at the expense of Russia, Turkey’s old antagonist. During the first months of the war Britain and its imperial allies conquered the bulk of Germany’s colonial empire.

During 1915 horrors multiplied. In Turkey the most appalling in a list of atrocities unleashed by the war occurred: the Armenian people endured an attempted genocide. On the western front a series of offensives by the British and French failed to dislodge the German forces. Similarly, in April the Turks repulsed an Entente attempt to seize the Dardanelles strait by landing at Gallipoli, and the invasion force withdrew in December. In May Italy was induced to enter the war on the Entente side but enjoyed no military breakthrough. On the eastern front German and Austro-Hungarian campaigns were more successful, and Russian Poland was occupied in the summer. Bulgaria entered the war on the side of the Central powers in September, and a subsequent German-led offensive in Serbia was also successful. An Entente counteroffensive from Salonika in Greece in October stalled, and British forces also retreated from Baghdad. Whereas the “war map” favored the Central powers, the Entente was successful in economic warfare. Britain’s decision to impose an economic blockade on Germany in March 1915 began the process of Germany’s internal debilitation.

The U.S. government encouraged citizens to buy war bonds. Library of Congress.

Vast battles of attrition, in a war now based upon industrialized killing, characterized the fighting in 1916. In the west both a German attempt to take Verdun, France (February–July), and a British counterattack at the Somme River in France (July–November) ended in costly failures. Romania entered the war on the Entente side in August but was soon overrun by German forces. A Russian offensive in the Austro-Hungarian province of Galicia (June–August) was more successful. A vast naval battle between the British and German fleets off the Jutland (Jylland) peninsula of Denmark in May had an indecisive outcome. German surface vessels, however, were unable to challenge the British blockade after that date. In addition, in response to U.S. pressure, Germany was

forced to moderate its use of submarines against merchant ships in the Atlantic. U.S. sales of war material, overwhelmingly to the Entente side, continued to grow. The Central powers again dominated in territorial terms in 1916, but the blockade steadily worsened shortages of domestic food and matériel.

In pursuit of unity at home, both sides promised their people that they were fighting defensive wars. Diplomatically, however, both sides made deals involving promises of annexations, either to shore up or to widen their alliances. By the Straits Agreement of March 1915, Britain and France promised Russia possession of Constantinople, Turkey. In April 1915, with the Treaty of London, Britain promised significant annexed territories on the Adriatic coast to Italy. In October 1915 Britain promised the Sharif of Mecca that Britain would support independence for the Arab peoples under Ottoman rule if the Arabs rose in revolt. The exact boundaries of future independent Arab states, however, were not made clear. In February 1916 France and Britain agreed to divide the bulk of the former German colonies. Under the Sykes-Picot Agreement of May 1916, France and Britain agreed on the partition of the bulk of the Ottoman Empire. Similarly, Germany prepared plans for annexations in both east and west in the so-called September Program of 1914. Germany's leaders of army and navy steadfastly insisted on annexations in Belgium and France for strategic security. In securing Bulgaria's adhesion to the Central powers in September 1915, Germany promised Bulgaria gains in Macedonia. Most importantly, in 1915 and 1916 Germany and Austria-Hungary also agreed on annexations in eastern Europe at Russia's expense. In a major step toward this goal, in November 1916 Germany and Austria-Hungary proclaimed a new kingdom of Poland, carved out of Russian Poland.

Politics Polarized

The war polarized politics. The increasing demands of war meant that liberal ideals were at a discount. From the political right in each warring nation arose pressures for more authoritarian policies and

an all-consuming military mobilization. The ultra-patriotic newspapers called incessantly for victory at any cost through the suppression of dissent, the expulsion of aliens, and radical economic nationalism. Politicians and military figures promising an intensification of the war rose to prominence and displaced moderates. For example, in Germany Generals Ludendorff and Hindenburg were appointed to the Supreme Command in August 1916. The two generals overshadowed the civilian government, and their political intriguing eventually secured the resignation of Chancellor Bethmann-Hollweg in July 1917. In Britain the Liberal government of H. H. Asquith steadily retreated from free speech, free service, and free trade. Conscription was introduced in January 1916. The Paris Resolutions, decided upon at an interallied conference of British, French, and Russian delegates in Paris in June 1916, threatened Germany with a postwar economic boycott. David Lloyd George, promising to wage war more vigorously until achieving a “knock-out blow” against Germany, displaced Asquith as prime minister in Britain in December 1916.

Nonetheless, in late 1916 diplomats attempted to resolve the war by negotiation. On 12 December, Germany offered to end the war by a diplomatic settlement. On 18 December, U.S. president Woodrow Wilson, a dedicated liberal internationalist, urged all sides to specify their war aims, hoping to increase pressure for negotiations. Britain, Russia, and France rejected the German offer on 30 December. Wilson pressed the case for “peace without victory” in a major address to the U.S. Senate on 22 January 1917. The Germans, however, undercut his effort, announcing a resumption of unrestricted submarine warfare for 1 February 1917. This resumption threatened the lucrative U.S. trade in war matériel with the Entente. Wilson cut off diplomatic relations with Germany. But not until the collapse of the czarist regime in the first Russian Revolution of mid-March did Wilson make his final decision on war. Characterizing the war as a democratic crusade, Wilson took the United States into the war against Germany on 6 April 1917.

Victory personified, holding a laurel and a sword, hovers over the soldiers in this World War I French war bond poster. Library of Congress.

During 1917 military stalemate persisted. Major campaigns were persisted with—in part to forestall rising public pressure for the revision of war aims and peace. The German U-boat war in the Atlantic was initially successful but was countered by the convoy system. The French attempted an advance in the west under General Nivelle in April, but this soon faltered, and mutinies followed. The Russians mounted a last major advance in July, but it ground to a halt within a fortnight. The British followed with a major offensive in Flanders, in Belgium (July–October), also to no avail. The Italians, too, suffered a major reverse at the village of Kobarid (Caporetto), Slovenia, in October. The British success in taking Jerusalem in December was one of the few Entente military successes in 1917. Only the promise of U.S. assistance gave grounds for hope.

In political terms rivalries intensified between the political right, demanding victory at any cost, and the

Library of Congress.

political left, now demanding peace by negotiation or revolution. In Germany widespread strikes were staged in April 1917 (and later in January 1918). German liberals and socialists seeking domestic reform and peace succeeded in passing the Peace Resolution through the Reichstag (parliament) in July 1917. The new Russian government pressed unsuccessfully for an interallied conference to revise war aims. European socialists proposed to hold a conference in Stockholm, Sweden, to draw up the basis of a compromise peace, but the western powers refused to allow their socialist parties to be represented. Britain experienced serious industrial unrest in April, and in August the British Labour Party swung around to support the idea of an international socialist conference at Stockholm. Faced with continuing disputes among moderate and revolutionary socialists, however, and the decisions of the U.S., British, and French governments denied passports to their socialist delegates, and the organizers eventually abandoned their efforts

to summon a broadly representative socialist conference in Stockholm. This intensified domestic political tensions still further. For example, the French socialist party left the government in September in protest at annexationist politics. The Papal Peace Note of August 1917 was one of many diplomatic opportunities for peace during the year. In Russia the Bolshevik Revolution of November eventually brought about an armistice on the eastern front in December.

War Aims Widened

Behind the scenes, however, diplomacy again widened war aims during 1917. In February, France and Russia agreed on gains at German expense in east and west in the Doumergue Agreement, and Britain and Japan agreed on the disposal of Germany's colonies in the Pacific. In April, Britain and France offered Italy a share of the spoils of the Ottoman Empire. At three conferences at Bad Kreuznach, Germany,

in April, May, and August 1917, again Germany and Austria-Hungary agreed upon annexations, principally in eastern Europe. On the other hand, diplomats made secret attempts at a diplomatic settlement. In September German Foreign Minister Kühlmann approached Britain, offering to give up Germany's gains in the west for a free hand in the east.

During the winter of 1917–1918 the peace talks between the Russians and Germans provided another opportunity for a general peace. The western powers resisted any peace of compromise brokered by socialists. Instead, in separate addresses in January 1918, Lloyd George (his Caxton Hall speech) and Wilson (his Fourteen Points speech) reaffirmed their liberal democratic ideals. Germany eventually imposed a harsh peace on the defeated Russians through the Brest-Litovsk Treaty of March 1918.

In spite of growing domestic discontent inside Germany, the German Army High Command insisted on a vast offensive to achieve a victory in France before U.S. troops could arrive in strength. The offensive was launched on 21 March 1918 and was initially successful. Allied counterattacks in July and August threw back the offensive, however, and an inexorable German retreat began. By September the military crisis was so serious that the German Army High Command buckled. A reformist government of liberals, democrats, and socialists was formed under Prince Max of Baden to pursue both domestic democratization and a negotiated peace. This government applied to Wilson for an armistice. The armistice was signed on 11 November 1918.

The consequences of the war for Europe and the rest of the world in the twentieth century were enormous. The war transformed the territorial boundaries of Europe: three great conservative empires—the Russian, the German, and the Austro-Hungarian—were swept away. New states were created in Eastern Europe, most notably Poland, Czechoslovakia, and Yugoslavia. Huge social changes were starkly revealed. The “socialism of the trenches” undermined notions of class privilege. Democratic expectations were heightened, but disenchantment followed. The idea of “separate spheres” in gender relations was both

In 1916 ultrapatriotic newspapers called incessantly for victory at any cost through the suppression of dissent, the expulsion of aliens, and radical economic nationalism. In this poster, which demands that the French “try again,” a young girl is solicited to support the war. Library of Congress.

challenged by women's wider experience of work and reinforced by war propaganda lauding masculine militarism. The war radicalized the political ideologies of the prewar era. Liberalism wilted. The schism between democratic and revolutionary socialists became unbridgeable. Communism, promising liberation from capitalism and imperialism, was catapulted into world politics. Fascism (and National Socialism) erupted in response, promising salvation from Communism through militarist values, authoritarian politics, and racial purity. The propaganda techniques so ruthlessly deployed during the war to manage the masses inspired the dictators of the interwar years. The enormous cost of the war, which produced huge internal and international debts, contributed to the persistent postwar economic dislocation. In cultural terms the war provoked a pervasive cynicism, tension between the generations, religious doubt, and a

After all my years of playing soldiers, and then of reading History, I have almost a mania to be in the East, to see fighting, and to serve. • **Wilfred Owen (1893–1918)**

profound antimilitarism. A vibrant and critical modernism emerged.

World War II

World War II (1939–1945) is regarded as the most widespread and deadliest conflict in human history. The war involved many nations and was fought on battlefronts in Europe, North Africa and the Middle East, Asia, and the Pacific. Led by Great Britain, the Soviet Union, and the United States, the Allies emerged victorious over the major Axis powers, Germany, Italy, and Japan.

World War II developed, in part, from the resolution of World War I. The peace conferences ending World War I resulted in a victor's peace, and the vanquished harbored a sense of unfair treatment. The worldwide economic depression that began in the 1920s and continued into the 1930s helped bring about totalitarian regimes in Italy, Japan, and Germany. When democracies could not agree on a forceful, common program to halt aggression in the late 1930s, war began; it expanded with the inclusion of the Soviet Union in June 1941 and the United States in December 1941. When the fighting finally stopped in September 1945, tens of millions of people had died worldwide; the great European colonial empires in Asia and Africa soon would end; and two great powers, the USSR and the United States, found themselves unable to bridge the divide between them and plunged much of the world into a Cold War that lasted until the collapse of the Soviet Union in the late 1980s.

The Build-Up to War

On 18 September 1931, the Japanese Kwantung Army claimed that Chinese bandits had blown up the main track of the South Manchurian Railway, and, within a

year, Japan seized control of Manchuria and created a puppet regime, Manchukuo. Japan then moved into Inner Mongolia and the Chinese provinces outside the Great Wall. In July 1937, minor hostilities expanded into war. Within several years, the conflict settled into a strange, three-sided affair, as Chinese Nationalist forces, Chinese Communist guerrillas, and the

Japanese army faced one another, with Japan largely controlling populated eastern China and the Yangzi (Chang) River valley, the Communists in their base area at Yanan, and the Nationalists at Qongqing in Sichuan Province.

Japanese aggression in Manchuria may have encouraged other dictators to disregard the League of Nations and to challenge the entire Versailles Peace Treaty structure. In January 1933, Adolf Hitler (1889–1945) became chancellor of Germany, and he expanded the army and navy, established an air force, and reoccupied the demilitarized Rhineland without serious protest from France or Great Britain. In March 1938, Hitler forced a unification of Germany and Austria—the Anschluss—and in September 1938 signed a peace accord with France and Great Britain that handed him the Sudetenland of Czechoslovakia. In March 1939, German forces seized Memel in Lithuania and took control of the remainder of Czechoslovakia. During the summer of 1939, France and Great Britain approached

the Soviet Union to assure Poland's territorial integrity, but the USSR shocked the world when it signed a treaty with Nazi Germany in late August.

Hostilities Begin

Hitler turned to war. On 1 September 1939, the German army unleashed a blitzkrieg against Poland, crushing the Polish army in three weeks. After a winter pause, Germany attacked Norway and Denmark on 9 April 1940, securing Norwegian ports and Swedish iron ore shipments. On 10 May 1940, Germany threatened a wheeling movement through the Low Countries and then struck through the supposedly impassable Ardennes forest, unleashing its panzer forces behind the advancing army, driving to the English Channel in several weeks. Only the valiant effort of British seamen lifting more than 300,000 British and Allied soldiers from Dunkirk prevented a complete German victory. Germany

The message on this Russian World War II poster by F. Gerling encourages Russian citizens to “subscribe to the 5½ % war loan. Build the road to victory.” Library of Congress.

turned south against France and forced the French surrender. Hitler apparently wanted to invade Great Britain, in Operation Sea Lion, and the Luftwaffe fought for control over the skies of Britain. Germany’s air force was designed for tactical support of advancing ground forces and not for a strategic air campaign, and it changed objectives too often—from coastal radar stations to fighter air bases to industrial factories, to terrorizing cities. By late summer 1940 the air offensive had failed. Strangely, from late summer 1940 until spring 1941, the German army launched no new offensives; this perhaps represented a major opportunity lost.

Germany next turned east. On 7 April 1941, Germany attacked Yugoslavia and Greece, and quickly conquered both countries. On 22 June 1941, Hitler sent more than 3 million German troops; 3,300 tanks; 7,700 artillery pieces; 2,500 planes; and forces from

satellite countries into the Soviet Union in Operation Barbarossa. Germany lacked accurate information on its enemy and greatly underestimated the challenge. But, in early summer, it appeared Germany would land the knockout blow: as its Army Group North drove on Leningrad, Army Group Center pulled off several huge encirclements of Soviet troops on the way to Moscow, and Army Group South neared Kiev. In late summer, the troops rested, and Hitler ordered the panzer forces of Army Group Center to turn north and south to help these peripheral drives. Turning south, tank forces of Heinz Guderian helped surround 665,000 Soviet troops near Kiev, the largest prisoner-of-war capture in history. When Germany resumed the advance on Moscow, the Soviet Union was ready. Operation Typhoon failed within sight of the Kremlin, and the Soviets counterattacked, catching the German army desperately unprepared. When the Soviet attack petered out in late winter, Germany had suffered grievous losses, and it seemed the Soviet Union could survive.

War in the Pacific

The Japanese defeat by the Soviets at the Battle of Nomonhan (Khalkin Gol) on the Mongolian border in August 1939 caused Japan to look south for raw materials; Japanese military leaders settled on a centrifugal offensive centered on the destruction of the U.S. Pacific Fleet at Pearl Harbor, Hawaii. On 7 December 1941, Japan attacked, and thereafter gained a series of striking victories, including capturing Hong Kong, the Malay Peninsula, and the British stronghold of Singapore, the Mariana and Gilbert Islands, the Philippines, Borneo, the Dutch East Indies, and other island groups to secure a vast resource area and territory behind which to defend these gains.

Japanese leaders, however, suffered from “victory disease,” and instead of building up their defenses in depth to withstand the American counterattack, they continued their offensive. They tried to isolate Australia and threaten India. The result was the flawed Japanese attack against Midway in early June 1942, which led to the destruction of

A “No Parking” sign in Rome during World War II. Allied forces entered the city on 5 June 1944.

four fleet carriers, fatally weakening the Japanese navy.

Russia Fights Back

Hitler returned to the offensive on the eastern front in summer 1942, but only had strength to attack to the south, aiming for Stalingrad and Soviet oil facilities by the Caspian coast. The distances exceeded German logistical capacity, and General Friedrich Paulus made a fateful decision to commit the German Sixth Army to a fight for Stalingrad. Under General Vasili Chuikov, the Soviet Sixty-second Army engaged in a valiant, desperate defense featuring house-to-house and even floor-to-floor resistance.

As the battle for Stalingrad raged from summer into the fall of 1942, General (later Marshal) Georgi Zhukov planned for a riposte, positioning vast Soviet forces on the vulnerable flanks of the German

position at Stalingrad; the Soviets intended to crash through Romanian and Hungarian positions, race around the German Sixth Army and Fourth Panzer Army, and effect a double envelopment. The Soviets struck on 12 November, and several days later the spearheads met at Kalach and cut off the Germans; in early February 1943, the last survivors surrendered. The Soviets followed this victory with an offensive that pushed the Germans out of Caucasia.

When the spring thaw halted operations, there was a bulge into German defenses around Kursk, and Hitler planned for a double envelopment to destroy Soviet positions after which, presumably, he would go on the defensive. But Hitler delayed the start of Operation Citadel many times, waiting for the new, heavy German tanks, and this delay allowed Zhukov to plan for the expected German advance. The greatest tank battle in history began on 5 July 1943, and the German pincer effort from the north quickly stalled; however, the attack from the south, featuring the cream of the German ground forces, made some headway before Hitler suspended offensive operations owing to the Allied invasion of Sicily. Thereafter, the Soviets seized the initiative and by early fall 1943 freed the eastern Ukraine of German forces; they continued advancing into winter 1943 into the western Ukraine, creating a huge bulge on the southern flank of German Army Group Center.

The force and space ratios on the eastern front clearly favored the Soviet Union. Had Germany not attacked at Kursk and had it dedicated its limited productive capacity to defense, German tactical superiority might have withstood Soviet logistical superiority. But Hitler threw away precious panzers and artillery at Kursk, and the Soviets halted operations only when their supply lines ran out.

On 20 June 1944, the Soviets launched Operation Bagration. The Soviet military achieved a great surprise, fooling German commanders in the east into believing that the attack would go south; the Germans concentrated their limited panzer resources there, largely leaving Army Group Center without tanks. The Soviets attacked, and surged past German positions before the infantry could react or retreat.

Generals think war should be waged like the tournaments of the Middle Ages. I have no use for knights; I need revolutionaries. • **Adolf Hitler (1889–1945)**

The advance carried from pre-1939 Russia all the way to the Vistula River and Warsaw in August, when Soviet forces outran their supply lines and halted.

In Air and at Sea

Meanwhile, on other fronts, the Axis powers retreated. To respond to Soviet calls for a “second front,” the United States and Great Britain opened a strategic bombing campaign. Before the development of long-range fighters, the U.S. Eighth Air Force, bombing in daylight, suffered heavy losses, while the nighttime Royal Air Force did little damage against German industrial targets. But Hitler wanted to maintain home front support and gradually withdrew fighter squadrons from the eastern front, and later from France and Italy, to defend Germany. After mid-1943 and the appearance of long-range American fighter planes, the outcome began to favor the Allies.

Similarly, the United States won the Battle of the Atlantic. At first, German U-boats enjoyed great success against the vulnerable American East Coast, and later in Caribbean and South Atlantic waters. Soon the United States constructed more cargo ships than the Germans could sink, and they built escort aircraft carriers, which accommodated only twenty

airplanes. The U.S. Tenth Fleet, organized around these carriers and their support ships, hounded German submarines, denying them open areas in which to operate and to surface for battery recharging. The Allies sank more than 80 percent of German submarines.

The Ground War

Finally, the Western Allies began to contest the German army. In November 1942, they launched Operation Torch against French northwest Africa to complement the British Eighth Army’s attack on Erwin Rommel’s Afrika Corps positions near El Alamein in the Western Desert of Egypt. By early May 1943 they forced the Axis surrender in Africa. On July 10, they launched Operation Husky, the invasion of Sicily, and after a six-week campaign crossed into Italy. The Italian government surrendered in September, and most Italian army divisions melted away. The Germans under Field Marshal Albert Kesselring defended well, and progress up the Italian peninsula was slow and costly, but the drain on German resources meant that German commanders could not count on reinforcements from other theaters. On 6 June 1944, the Allies launched Operation Overlord,

Charles de Gaulle inspects troops in North Africa after American and British forces freed the region from German control.

U.S. troops waded through water and German gunfire at Normandy on D-Day, 6 June 1944. FDR Library.

the invasion of France, commanded by U.S. army general Dwight Eisenhower. Three airborne divisions landed during the night, and five infantry divisions assaulted five beaches: Gold, Sword, Juno, Omaha, and Utah. Despite the difficulty of the hedgerows in Normandy, the Allies brought men and equipment ashore in the expanding beachhead. In late July 1944, the U.S. army launched Operation Cobra; as American forces moved down the Cotentin Peninsula to Avranches and broke out and around the German defense, the U.S. Third Army under General George Patton became operational, and it quickly spread west into the Brittany peninsula and east toward the Seine above Paris. German troops were surrounded near Falaise, and an invasion in southern France, Operation Dragoon, sent American and Free French troops up the Rhone River Valley to meet Patton's forces near Dijon, cutting off German forces in France.

After Midway, the United States seized the initiative against Japan. At first, it was the desperate fighting on Guadalcanal from August 1942 to February 1943, and then the U.S. advanced on two axes. Admiral Chester Nimitz led the navy advance to the Gilbert Islands and Tarawa in November 1943, to the Marshall Islands and Kwajalein in February 1944, and then to the Marianas in June 1944, and the invasions of Guam, Saipan, and Tinian along with the

Battle of the Philippine Sea (also called the Marianas Turkey Shoot). Army general Douglas MacArthur commanded a mixed force that moved up the Solomon Islands chain and leapfrogged Japanese strongpoints on the New Guinea coast, while isolating the 100,000-man Japanese Army in Rabaul in New Britain. In October 1944, MacArthur invaded the Philippines, although fighting would continue there until war's end. Meanwhile, the Central Pacific offensive moved to Iwo Jima in the Bonin Islands in January 1945 and Okinawa in the Ryukyus in April 1945.

The attack on the Philippines cut off Japanese forces in Southeast Asia, and an Anglo-Indian offensive pushed the Japanese through Burma, though progress, owing to the difficult terrain, was slow. Meanwhile, Chinese government forces managed to occupy a great many Japanese divisions while conserving strength for the expected renewal of the civil war with the Communists.

Victory in Europe

In fall 1944, the pressure on Germany continued. Strategic bombing of Germany caused many casualties, although Albert Speer achieved a production miracle for war goods. The Red Army paused in the center, sweeping into the Balkans and trapping

Civilians salute and welcome a division of the French army returning to France circa 14 August 1944 after resisting German attack. National Archives.

the Germans along the Baltic. By December 1944, the Soviets were at the 1939 German-Polish border and near Budapest in Hungary waiting to resume the offensive. In the west, Eisenhower ordered a halt in operations for winter, owing to supply difficulties. In late December 1944, Hitler launched a desperate gamble, an attack against weak American forces in the Ardennes, hoping to drive toward Antwerp, cut off the British, and force the Americans to surrender. But the German attack lacked sufficient fuel reserves; the Americans, especially around Bastogne, defended fiercely, and when skies cleared Allied airpower battered German formations. As the Soviets launched a winter offensive, the Allies drove to the Rhine and in March 1945 crossed, first at Remagen, and then along the upper Rhine and finally to the north. Meanwhile, the Red Army drove on Berlin, and Soviet forces under Zhukov and Marshal Ivan Koniev engaged in a race to Berlin, which was won by Zhukov's men at terrible cost. In late April elements of the U.S. and Red armies met at Torgau on the Elbe, and Germany was divided. Hitler committed suicide in his underground bunker in Germany, and on 7 May, German commanders surrendered to Eisenhower in Rheims, France, followed on 8 May 1945, with a surrender to Soviet commanders in Berlin.

Japan Surrenders

The Japanese continued to resist, and American experts predicted a bloody and costly attack on the Japanese home islands. However, in July 1945, at Alamogordo, New Mexico, scientists exploded the first atomic bomb, and several weeks later the United States dropped an atomic bomb on Hiroshima (6 August) and one on Nagasaki (9 August), compelling Japan's surrender on 2 September 1945 in Tokyo Bay. World War II ended.

Aftermath

The end of World War II brought with it a wide range of significant consequences, many of which were aimed at preventing similar conflicts in the future. War crimes committed by the Axis powers, including the Holocaust, were addressed at the Nuremberg Trials and the Tokyo War Crimes Trial. The United Nations was established with the explicit aim of maintaining international peace and security. The Universal Declaration of Human Rights was instituted as a guarantee of the rights for all human beings. The international economic and financial architecture was overhauled and increasingly managed and regulated by the World Bank, the International Monetary Fund,

and the World Trade Organization (formerly the General Agreement on Tariffs and Trade). The state of Israel was established. Many former colonies won their independence, while other states such as Germany and Korea were divided ideologically and politically. Women began to find new and expanding roles in society on the back of their important contribution to the war effort. War-time technologies, innovations, and management systems were put to good peacetime uses, few more important than the jet engine and the now indispensable computer. Particularly important, learning from the mistakes of the interwar period, Europe (including Germany) was rebuilt under the Marshall Plan, as was Japan, which would soon modernize and rise to major economic power status.

Writing Systems and Materials

Throughout history, writing has played a significant role in the generation of knowledge, the advancement of ideas, and the growth of societies. While many of the details concerning the development of writing remain a mystery, there is sufficient evidence to trace some of the major stages in the evolution of writing and to examine the great variety of writing systems and materials that have been, and continue to be, developed.

Some have argued that the very earliest evidence of written communication comes in the form of paintings of animals on cave walls found in southern France and dated to the Ice Age some twenty thousand years ago. Such artistic representations may have been used to convey ideas about both the mysteries and rhythms of the natural world or to provide a narrative—in visual form—describing the relationship of humans to their immediate environment. Several of these paintings bear very distinctive markings, such as dots, signs resembling body parts (e.g., the human hand), and symbols reminiscent of the letter *P* in the English alphabet. Indeed, a variety of unusual prehistoric symbols have been found that may well support the claim that some form of written communication has long been an essential feature of the larger human experience.

Ancient Writing

Many credit the Sumerians of ancient Iraq with the creation of the first formal system of writing circa 3500 BCE. In its very earliest stages, it consisted of numerical symbols and pictographs—that is,

simple visual representations of objects in the natural world—etched on clay tablets, which were then dried or baked for the purposes of preservation. At first, a pointed reed stylus appears to have been used by Sumerian scribes. Later, three significant developments in written Sumerian would occur. The first was the rotation of the original pictograms ninety degrees in a counterclockwise direction; it has been suggested that this modification facilitated ease in writing. The second, a shift to an angled (or wedge-tipped) stylus, can be classified as a technological change. The reason for this change is not known; however, it enabled the original pictograms to be rendered with a series of wedge-shaped, or cuneiform, impressions made on the usual soft clay medium. The third was the radical simplification of these cuneiform signs so that in time they bore little resemblance to their pictographic progenitors. Initially, these signs were baroque in detail, and the intent seems to have been to reproduce, to the extent possible, a cuneiform version of the original pictogram. In time, this no doubt proved to be untenable and unnecessary as the administrative demands on scribes—and their familiarity with the writing system itself—increased. This change may have accompanied a concomitant development in which the original pictograms came to stand for Sumerian lexemes (whole words), morphemes (distinct parts of speech used to form words and delimit syntactic relationships), and phonemes (distinct sounds used to form morphemes and lexemes). Furthermore, this move toward simplification and abbreviation may be related to another phenomenon—the minimalist tendency in Sumerian writing.

Scholars have noted that Sumerian texts are sometimes written in a very terse style in which certain

Rock carvings such as this one, made by ancient Native Americans in New Mexico, as well as cave paintings depicting animals, are considered to be among the earliest forms of written communication.

parts of speech are excluded. It has been suggested that this might be an indication that the written text itself was intended to serve as a mnemonic device to jog the memory of the reader, who would possess the ability to fill in the existing gaps. Some feel that the ancient Near Eastern antecedent to the Sumerian writing system consisted of inscribed clay tokens and *bullae* (clay envelopes) into which the aforementioned tokens were inserted. The earliest of these have been dated to 8000 BCE and may have been used as media of economic exchange and for record-keeping purposes. The shapes and etchings that these tokens and *bullae* bear may have served as the foundation upon which the Sumerian writing system was built.

Hieroglyphic writing, which also began as pictographic and later gave rise to several alternative forms (including Hieratic, Demotic, and Coptic), was

developed in Egypt also during the fourth millennium BCE (c. 3000 BCE). Harappan civilization in the Indus Valley also spawned a distinct writing system of its own circa 2500 BCE consisting of a combination of pictographs and symbols. In addition to these very ancient exemplars, many additional writing systems were created in early antiquity. These include: Proto-Elamite (c. 3050–2900 BCE, Iran); the Phaistos Disc script, Linear A, and Linear B (nineteenth, eighteenth, and fourteenth centuries BCE respectively, Crete); Proto-Sinaitic (early second millennium BCE, Egypt); Cretan Hieroglyphic (c. 2100–1700 BCE); Ugaritic (fourteenth century BCE, Syria); Oracle-Bone Script (c. 1300 BCE, China); Hebrew (c. tenth century BCE, Israel); Brahmi and Karosthi (c. 300 BCE, India); Etruscan (eighth century BCE, Italy); Zapotec (sixth century BCE, Mexico); Epi-Olmec/Isthmian (second century BCE, Isthmus of Tehuantepec, Mexico); Mayan (c. 500 BCE, Mexico); Meroitic (c. fourth century BCE, Sudan); Phoenician (tenth century BCE, Lebanon); and Greek (c. eighth century BCE).

Others could be added to this list, but this selection is sufficiently representative to give an idea of the antiquity and tremendous diversity of the world's writing systems.

From a historical perspective, it would not be an exaggeration to say that written communication has been an essential part of human interaction and a major factor in the development of complex societies. Writing remains a vital part of twenty-first-century life, and new systems, media, and technologies continue to be developed. One recent encyclopedia lists some four hundred distinct writing systems (past and present) from around the world, a clear attestation that writing is a global rather than an isolated human phenomenon.

Analyzing Writing Systems

A number of different typologies are used in the classification of writing systems, each of which is based on theoretical assumptions about the manner in which they function, their relationship to spoken

Action, looks, words, steps, form the alphabet by which you may spell character. • **Johann Kaspar Lavater (1741–1801)**

languages, and the particularities a given categorization scheme is designed to highlight. For some, a distinction is made between semasiographic and glottographic systems. The former uses visual images to indicate ideas directly, while the latter employs signs as representations of actual spoken sounds. Others make a distinction between protowriting (e.g., systems using pictograms) and full writing, the latter of which can be further subdivided into syllabic and consonantal systems. Still others make a distinction between pleremic and cenemic writing. Pleremic systems use written signs to denote morphological essence and lexical meaning. The cuneiform writing system of ancient Sumer would be one example of this type of writing. Cenemic systems use signs to represent distinct phonological units only. The Phoenician, Greek, Latin, and English alphabetic scripts are cenemic in nature.

Surfaces used for written communication have been and continue to be determined in part by the raw materials available in a given geographical location, the genre and purpose of that which is to be written, and the cultural conventions governing the art of writing. There is evidence from around the world for the use of the following: bone, skin (human and animal), shell, rock, clay, textiles, bamboo, bark, cut stone, metal (precious and base), ceramic fragments (i.e., broken pottery), leather, papyrus, parchment, paper, and electromagnetic storage devices. Methods of writing include carving, stamping, painting, engraving, chiseling, burning, sewing, weaving, spraying, incising, and tattooing. Implements used in writing have varied widely and continue to do so. Some of the more important are rocks, reeds, rushes, brushes, quills, pens (with an assortment of metal and fiber tips), graphite pencils, chalk, wax crayons, and electronic data entry devices (e.g., computer keyboards or microphones used in conjunction with voice-recognition software that transforms spoken words into electronic text). Technological advances, the emergence of new forms of writing, and the adaptation of norms in written expression are just a few of the factors contributing to such change.

Close examination of the world's many writing systems reinforces the importance of three general maxims. Those seeking to understand the development of writing within a global context should keep them in mind. The first is that writing systems are as varied as the societies in which they are produced. The second is that written communication is governed by the same social, political, religious, and artistic conventions that influence the creation of other cultural artifacts. The third is that while there are historical data that enable one to trace the diffusion of writing systems in geographically contiguous areas or propose theories that account for their spread through trade, colonization, and other forms of cultural contact, there remain many unanswered questions about the development of writing. Following are a few of

Written Chinese characters, which comprise ideograms and pictograms, provide a visual expression of a concept or an object in a way that purely phonetic scripts do not.

Do not consider it proof just because it is written in books, for a liar who will deceive with his tongue will not hesitate to do the same with his pen. • **Maimonides (1135–1204)**

the more important. Are there psychological factors that elicit written communication? Is there a communicative impulse in humanity that can only be given full expression in writing? What is the relationship between pictographic writing and other forms of visual artistic expression? To what extent have social elites been responsible for creating systems of written communication, and in what ways have such systems contributed to the establishment of political and religious institutions?

Furthermore, there are some equally challenging questions that remain about contemporary writing systems, many of which are the offspring of the ancient precursors noted above. These deserve additional attention. Are alphabetic writing systems limited in their capacity to convey certain concepts and ideas? Do pictographic systems increase or decrease overall literacy rates? In light of global socioeconomic and political trends, and in the absence of an international lingua franca, do pictographic writing systems offer a more accessible and effective means for communication across cultural and linguistic barriers?

There are, of course, no simple answers to these questions. In addressing them, however, one can shape an agenda for the study of writing in the future that is methodologically sound and open to contributions from the social sciences and the humanities.

It is clear that writing will figure prominently in twenty-first-century communication. It may be that the future will witness the creation of new and experimental writing systems aimed at promoting justice, egalitarianism, mutuality, and other values needed to sustain our global community.

(1360–1424)

THIRD EMPEROR OF CHINA'S MING DYNASTY

Zhu Di, son of the founder of the Ming dynasty, usurped the throne from his nephew in 1402 to become the Yongle emperor. During his reign he extended the power and influence of the dynasty, commissioned naval expeditions to the Indian Ocean, moved the imperial capital to Beijing, and oversaw important scholarly enterprises.

The Yongle emperor (reigned 1402–1424) of the Ming dynasty (1368–1644) was one of the most dynamic and aggressive rulers of China. Committed to ventures on a grand scale, he influenced China and East Asia for generations to come. He extended Chinese power to Mongolia and Vietnam, dispatched great maritime expeditions to the Indian Ocean, launched massive literary projects that shaped the culture of the Chinese elite, reorganized the imperial bureaucracy, and constructed a new imperial capital.

Yongle (actually his reign title, though it is the name he is most frequently known by; the family name of the rulers of the Ming was Zhu and Yongle's personal name was Di) originally was not destined for the imperial throne, however. His father, the Hongwu emperor (reigned 1368–1398), the founder of the Ming dynasty, designated his eldest grandson as his successor. But the Jianwen emperor (reigned 1398–1402), Yongle's nephew, lacked Yongle's shrewdness and military expertise. Within a year of Hongwu's death, Zhu Di rebelled against Jianwen and led his troops to victory over the emperor's forces. In all likelihood, Jianwen died when the imperial palace in Nanjing caught fire. At the age of forty-two, Zhu Di ascended the throne on 17 July 1402 as the Yongle (Perpetual Happiness) emperor.

Historians generally agree that Yongle's reign represents a second founding of the Ming dynasty, a significant transformation of policies established by Hongwu. Like his father, Yongle distrusted the Confucian scholar-officials who headed his bureaucracy; but, in the interest of stable rule, he restored ministries that Hongwu had abolished and allowed civil officials considerable independence in daily affairs. He moved the capital to Beijing, near his northern power base, and employed 1 million workers in its reconstruction, which included the building of the Forbidden City, now the principal relic from his reign. To bolster civil officials in the capital and provinces, Yongle ordered the compilation of two compendia of texts and commentaries of Confucian classics that became standard works for preparing for the civil-service examinations. He also commanded more than two thousand scholars to produce *The Great Encyclopedia*, a compilation of accumulated knowledge that ran to about eleven thousand volumes (or 50 million words). Gargantuan in scale, it proved so expensive to reproduce that large parts of it were lost long after its completion in 1408.

In his government reforms and literary projects, Yongle performed as a traditional Chinese sovereign. But in his foreign policy, he employed military commanders and the burgeoning eunuch establishment. He was a warrior, matched only by Khubilai Khan (reigned 1260–1294), the first emperor of the Yuan dynasty (1279–1368) in his militarism. Commanding armies some 200,000 men strong, he invaded the steppes repeatedly after 1410, inflicting defeats on Mongol khans three times though he was unable to duplicate certain successes. These campaigns wore him out, and he died retreating from Mongolia in

1424. Relying on his offensive policy, he withdrew military posts on the northern border that had been established by Hongwu, leaving China vulnerable to attack in the absence of an emperor as warlike as himself. To some extent, the defensive perimeter of the Great Wall, a late Ming construction, was a consequence of Yongle's bellicose military strategy more than a century earlier.

In 1406, Yongle ordered an expeditionary force of two hundred thousand men to invade Annam (in present-day northern Vietnam), an audacious attempt to incorporate the area into the empire. Successful for a time, Chinese aggression eventually provoked native resistance, and Yongle found his armies harassed by guerrilla warfare. After twenty years of casualties and expense, the Chinese were driven out by 1427. At the same time as the Vietnam imbroglio, Yongle took the

action for which he is now most famous: he dispatched the largest maritime expeditions the world had ever seen. From 1405 to 1424, six fleets, sometimes comprising two hundred ships and as many as twenty-eight thousand men, sailed to Southeast Asia, India, Iran, Arabia, and East Africa. Commanded by the famous eunuch-admiral Zheng He (1371–1435), the expeditions were simultaneously displays of Chinese majesty, attempts to impose Chinese suzerainty (especially in maritime Southeast Asia), and commercial ventures aimed at suppressing private Chinese seaborne trade.

On all fronts—Mongolia, Vietnam, the voyages of Zheng He, the reconstruction of Beijing—Yongle vastly overextended Chinese resources, draining the treasury and causing widespread discontent. He ruled with an iron fist, putting his extraordinary ventures in the hands of military men and eunuchs, groups repugnant to the Confucian elite. He left the empire weakened before Mongol attacks; he stimulated a Vietnamese nationalism that soon proved deadly to neighboring kingdoms; and he insured that no future emperor would seek to dominate the southern seas. Autocratic, resolute, and daring, Yongle had a brilliant reign but left his successors a troubling legacy.

Zheng He was a diplomat, explorer, and fleet admiral who, between 1405 and 1433, made seven voyages to the Indian Ocean. His expeditions and four naval and land battles brought more than thirty kingdoms into the Chinese economic sphere.

Zheng He commanded seven great maritime expeditions dispatched by emperors of China's Ming dynasty (1368–1644) to Southeast Asia, India, Iran, Arabia, and East Africa between 1405 and 1433. The fleets were launched by the Yongle emperor (reigned 1402–1424), although the last expedition in 1431 was ordered by the Xuande emperor (reigned 1426–1435). Yet Zheng He, an imperial servant and Muslim eunuch, eventually became more renowned than those formidable sovereigns. He is regarded as a tutelary deity in Indonesia, as a folk-hero in fiction of the Qing dynasty (1644–1911), as an exemplary patriot in textbooks of the People's Republic of China, and as the Chinese counterpart of Vasco da Gama (c. 1460–1524) and Christopher Columbus (1451–1506) in modern studies of world history. A recent work even makes the fantastic claim that his captains discovered and colonized America and Australia in 1421.

A native of Yunnan in southwestern China, Ma He (as Zheng was born) traced his descent from Sayyid Ajall (c. 1210–1279), a Muslim from Bukhara (in contemporary Uzbekistan) who governed the province for Khubilai Khan (reigned 1260–1294), founder of the Yuan dynasty (1279–1368). When the Ming conquered Yunnan in 1381, the eleven-year-old Ma was among many boys castrated and enrolled in the eunuch establishment of the dynasty. Enterprising

and competent, Ma commanded troops under the future Yongle emperor. As a reward for Ma's valor in a crucial encounter, the emperor gave him the name Zheng, the name of the battle site.

When the emperor commissioned his maritime expeditions, he placed Zheng He in command, entrusting him with the powers of a viceroy. Typically comprising some two hundred ships and twenty-eight thousand men, the fleets indisputably were the greatest the world had ever seen and included the largest wooden ships ever built. But debate persists about everything else, such as the dimensions of the biggest vessels, called treasure ships, the nature of the navigation charts employed, and the timing and destinations of particular voyages. Above all, there is no consensus on the purpose of the mammoth expeditions. In part, confusion and mystery surrounds them because of the opposition they encountered among Confucian scholar-officials of the empire, a powerful group that deplored the eunuchs in control of the fleet. In 1477, when a prominent eunuch administrator proposed a renewal of the voyages, Confucian ministers ordered destruction of the records of the Yongle venture.

While this was a grave loss to history, the ambitions of the Yongle emperor suffice to explain the task he gave Zheng He. Having usurped the throne from his nephew, the Jianwen emperor (reigned 1398–1402), Yongle sought a warrant of legitimacy by enrolling tribute clients abroad, a task made effortless by display of awe-inspiring force. An aggressive and militaristic ruler, he led five campaigns against Mongol khans and, in 1406, he ordered the invasion of Vietnam. The fleets complemented this last endeavor, with the Ming sovereign curbing the power

of kingdoms in Java and Thailand while also providing an umbrella of protection over the port of Melaka and those of the northern Javanese coast. Given his large and experienced army, Zheng He naturally met little opposition. In 1407, he intervened in a struggle for power in the Majapahit kingdom of Java, and soon after, his troops destroyed ten pirate ships and killed numerous followers of Chen Zuyi, the Chinese chieftain of Palembang in Sumatra. In 1411, Zheng fought off an attack by Vira Alakasvara, the monarch of Sri Lanka (Ceylon), and shipped the hapless ruler to captivity in China.

These forceful actions cannot be separated from the commercial dimensions of Zheng He's voyages. In the interests of imperial security, Yongle aspired to suppress Chinese private seaborne trade; hence Zheng's ships came loaded with Chinese commodities, especially silk and porcelain, goods to be sold

to eager customers as well as gifts to be bestowed on compliant rulers. The junks returned to China laden with black pepper, spices, sandalwood, precious stones, Indian cottons, and exotic animals (especially giraffes and elephants).

Whether acting as admiral of the fleet, troop commander, or trade commissioner, Zheng invariably was an agent of Yongle, not an adventurous explorer in search of new sea routes and undiscovered lands. Less significant in world history than Columbus or da Gama, Zheng loyally and capably obeyed the will of his sovereign. After Yongle died, there was only one more expedition, ordered by Xuande to take tribute envoys back to their kingdoms. In all likelihood, Zheng He died on this final voyage, and he perhaps is buried near Nanjing, not far from where his treasure ships departed for the southern seas.

Zhu Yuanzhang

(1328–1398)

FOUNDER OF CHINA'S MING DYNASTY

Zhu Yuanzhang rose from a life of suffering and adversity to become one of the most powerful and autocratic emperors in Chinese history. His thirty-year reign as founder of the Ming dynasty (1368–1644) was characterized by two radical policies: the most far-reaching, innovative agrarian reforms prior to those of Mao Zedong in the mid-twentieth century; and a despotic control of government characterized by bloodthirsty and terrifying purges.

Zhu Yuanzhang, the founding emperor of the Ming (Bright or Radiant) dynasty (1368–1644), reigned from 1368 to 1398 with the reign title Hongwu (Vast Military Power); his posthumous abbreviated title is Taizu (Grand Progenitor).

Zhu Yuanzhang was the third son of an impoverished peasant family living in Haozhou County along the Huai River in present-day Anhui Province. When he was a teenager, a combination of drought and plague carried off his parents and oldest brother, leaving him destitute. Neighbors helped him find refuge at a Buddhist temple, where he became a monk. But after a few weeks the temple ran out of food and he was forced to leave and go begging in the countryside.

For three years the famished and unprepossessing youth roamed around east central China observing the effects of famine and dynastic breakdown on farming people. During that time he became associated with the subversive Red Turban movement, whose goal was the overthrow of the Mongol Yuan dynasty (1279–1368). He then returned to his temple and worked on improving his reading and writing skills. In 1352, when government forces burned down the

temple, he joined a Red Turban rebel unit. Rising rapidly through the ranks, he assembled a fighting force and branched out on his own. He developed a base in the lower Yangzi (Chang) River region and in 1356 captured the strategic city now called Nanjing.

During this period of civil war Zhu built up his armed forces, attracted scholars to his side, and established himself as an imperial contender. Thanks to growing popular support and outstanding military aides he was able to defeat all other claimants and become the only supreme ruler in Chinese history to rise to power from a destitute background. In 1368 he declared himself emperor. Before the year was out his forces had driven the Mongol rulers out of their capital (present-day Beijing) and sent them fleeing back to Mongolia.

Emperor Zhu established a harsh but powerful autocracy. He had risen to the top through military power and iron discipline. He recognized the need to rely on the educated elite to install a civilian regime. But as a once destitute peasant he maintained a seething distrust of such people, and as a contender for power he was suspicious of opposition and ready to suppress it at all costs. His thirty-year reign was characterized by two radical policies: first, the most far-reaching and innovative agrarian reforms prior to those instituted by Mao Zedong in the mid-twentieth century, and second, a despotic control of government characterized by bloodthirsty and terrifying purges.

As an agrarian reformer, the new emperor was driven by the desire to restore peace and production to the rural people. More than any other ruler before his time, Zhu identified with peasants and sought to ameliorate their lives. Throughout the north China

plain he moved hundreds of thousands of people, many of them stranded by the civil war, back onto abandoned land. In 1374 alone 140,000 households from eastern China were resettled in the emperor's native region. Then he initiated intensive surveys of the tax and landholding systems in this prime agricultural region. The tax information was recorded in yellow-bound registers and the landholding information in "fish scale" registers, so named because of the contours of the land charts. These registers, copies of which were maintained in central and local government offices, constituted the most thorough land survey in China prior to modern times. Although comparable to the Domesday survey carried out across England in the eleventh century by William the Conqueror, they were far larger in scope and consequence.

In addition the emperor installed a method of rural fiscal government, known as the *li-jia* system. Under this system, households were organized into groups of 110, representing a *li* (administrative

neighborhood). The ten wealthiest families were appointed to serve annually as leaders of the *li*. The remaining families were divided into ten *jia* (units of ten families). Each of these *jia* families also served annually as head of their *jia*. Small family units were included as add-ons. Later in his reign the emperor introduced an overlapping system of neighborhood elders (*li-lao*) to handle local disputes and offenses and punish mischief-makers.

The main aim of all this rural surveying and organization was to equalize the land and labor tax burden and get registration and collection of taxes out of the hands of rapacious bureaucrats and into those of producers. The neighborhood elder system was intended to prevent local officials from exploiting crime as a source of income and patronage. Elders were required to uphold social values (such as respecting and honoring one's parents), and to promote agricultural work and water conservation. If they had complaints, they were authorized to visit Nanjing and report them in person. An important piece of this agrarian policy was the establishment of agricultural colonies to support the emperor's military forces, thus ensuring that the latter would not be dependent on the rural fiscal system. Throughout his reign the emperor continued to refine these initiatives.

Emperor Zhu's harsh policies toward officials and educated people grew out of his experience of oppression and hardship as a youth. As ruler of all under heaven he deplored waste and hated ostentation. When a serious drought struck eastern China shortly after his accession, he clothed himself in white mourning dress and straw shoes and prayed for several days out in the open until the rains came. These austere attitudes carried into the organization of the bureaucracy. He reduced the complement of local officials, subjected them to intense scrutiny and cast doubt on their integrity. But it was the central government officials who suffered most from the emperor's aspersions. Several purges were carried out in which thousands of officials and their families suspected of corruption or treachery were rounded up and put to death. A famous poet, whose words were construed as criticism, was sliced in half. In numerous ways

underperforming and unlucky officials were derided, humiliated, and on occasion publicly flogged. Only the Empress Ma, a woman of great strength and magnanimity, was capable of restraining the emperor's anger. After she died in 1382, he lived on alone and embittered.

A unique aspect of Emperor Zhu's rule was the establishment of his administrative capital in Nanjing, itself an ancient capital during early periods of disunity. He built the city into a formidable fortress surrounding the imperial quarters, with everything positioned to take advantage of the location's geomantic and strategic features. Nanjing gave access to the crucial eastern China region on which the regime depended for its fiscal resources. It also enabled the emperor to control wealthy localities that had supported other contenders. After Emperor Zhu died, the usurping Emperor Chengzu (Zhu's fourth and oldest surviving son) moved the main capital to his base in north China, henceforth named Beijing (Northern Capital; Nanjing, in contrast, means Southern Capital). Nanjing remained an important administrative

center and would again serve as a capital during the massive anti-Manchu Taiping Rebellion (1851–1864) and in the Nationalist era (1928–1949).

Zimbabwe, Great

The state of Great Zimbabwe flourished circa 1290 to 1450 in southern Africa. The ruins of its capital, which was built from massive walls of stone, reflect the grandeur and exquisite workmanship of the original. The state was ruled by a small political elite that also controlled networks in the Indian Ocean trading economy as an exporter of gold.

Visitors to the ruins of the former capital of Great Zimbabwe, a state that flourished in southern Africa from approximately 1290 to 1450, may be struck by two observations. First, the impressive stone structures emerging from the savanna still convey the former wealth and importance of the site. In the local language, Shona, *zimbabwe* means “houses built of stone,” and there are many *zimbabwe* in the region, in particular in the area bounded by the Limpopo River in the south and the Zambezi River in the north. Great Zimbabwe thus represents a prominent example of political power and architecture; in fact it was the largest stone structure in Africa south of the Sahara built before European colonization in the late nineteenth century. While having only extended across a fraction of what today is the national territory, its legacy is so important that in 1980 the newly independent country was named Zimbabwe, and the image of an artifact, the stone-carved Zimbabwe bird, of which eight were found at the site, became part of the national flag.

Second, a visitor not too familiar with the history of Great Zimbabwe is likely to be surprised by the artifacts exhibited at the museum on site. These range from locally produced tools to luxury items from the Indian Ocean rim, such as glass beads from India

and porcelain from China. Despite Great Zimbabwe’s location several weeks’ march by foot from the coast, the political centralization that led to its formation was based on its links with the Indian Ocean economy, exporting gold in exchange for cotton cloth and luxury items.

Origins

Great Zimbabwe’s cultural achievements, wealth, and economic success, expressed in its stone architecture, so gravely contradict prejudiced notions of the African past that since the 1870s, a range of European travelers, archaeologists, and historians, have attributed them to outsiders. In particular, the white-settler regime during the colonial period (1890–1980) claimed that some allegedly superior civilization, such as the ancient Egyptians or the Phoenicians, must have been responsible. Ironically, however, already in the early twentieth century, archaeologists had proved that local Shona-speaking people had built the city.

As is the case elsewhere with agricultural societies, the origins of Great Zimbabwe as a centralized political state lie in its participation in long-distance trade networks, which generated sufficient wealth to sustain a political elite in a highly stratified society. Its rich gold deposits made the region so attractive to Swahili-speaking traders from the East African coast that in the thirteenth century caravan routes were established with Kilwa in East Africa, which became Great Zimbabwe’s most important trade partner on the Indian Ocean rim. Great Zimbabwe was thus incorporated into the Indian Ocean economy, exchanging precious metals, especially gold and from the fourteenth century also copper, for cotton cloth and

luxury items. The political elite controlled the long-distance commerce by taxing traders and through its networks of patron-client relationships with miners and agriculturalists. These networks rested upon the redistribution of accumulated wealth, particularly in the form of cattle. The unusually high population density at the capital city and division of labor within the state depended on sustainable agriculture. A shared religion manifest in ancestral worship and reverence of a high god contributed to political unity, which was further cemented through the authority of a king, advised by a group of male elders.

The City

Importantly, as the Zimbabwean historian Innocent Pikirayi points out, the capital of Great Zimbabwe was not merely a large village, but indeed a metropolis. Different population strata lived in close proximity, and the layout as well as architecture expressed power relations. In contrast to Zimbabwe elsewhere, where the walls functioned as defense structures, here they served to mark the city's three distinct areas. There is a hill complex, an elevation of granite rocks with steep slopes. On top, surrounded by a wall, were the living quarters of the king and his court. Interestingly, there is no water source inside this structure.

Thus, while access to this hilltop could easily be controlled by a few guards, it could not have withstood a siege for any significant period of time. At the bottom of the hill complex is the so-called great enclosure, where members of the political elite and traders, or as some historians suggest, the royal women, used to live. Today, most of the surrounding high wall, more than five meters tall, is still in place, with a massive stone tower inside. The religious or political purpose of this tower is debated. Between the hill complex and the great enclosure and beyond extends a valley, where the agriculturalists lived in the open savannah. All houses were at the time round huts constructed of mud and wattle. It is safe to assume that the city thus represented the wealth and power of the state, unifying its inhabitants while at the same time reasserting social stratification.

Decline

Two factors contributed to the decline of Great Zimbabwe in the fifteenth century. Most significantly, its elite lost control over the gold trade to competing states, especially to Munhumutapa further to the north, which rose to power in the mid-fifteenth century. Subsequently, the caravan routes were relocated and the region was cut off from the Indian Ocean trade. Secondly, the relatively high population density in an area with only one annual rainy season eventually caused much environmental stress. At Great Zimbabwe's peak up to 18,000 people lived in the city, extending over an area of approximately 720 hectares. Once the state could sustain its elite no longer, the city lost its purpose. Out-migration occurred, and political decentralization eventually led to the fragmentation of the state into small-scale local communities and the rise of states elsewhere in the region.

Implications

As a city built of stone, with a small political elite deriving its power from controlling the state's incorporation into the Indian Ocean economy through the

*If there are dreams about a beautiful South Africa, there are also roads that lead to their goal.
Two of these roads could be named Goodness and Forgiveness. • Nelson Mandela (b. 1918)*

export of gold, Great Zimbabwe represents common patterns of state building in the region between the tenth and nineteenth centuries. Great Zimbabwe's decline was typical for agricultural societies elsewhere, deriving from the ecological crisis caused by population concentration and its marginalization from long-distance trade. However, unique in the region is that the layout and the architecture of the city did not appear to have served defense purposes at all and instead were an expression and re-inscription of power relations between population groups.

Zionism

Zionism is a movement to establish a homeland for Jews who have been scattered throughout Europe. The word Zion refers to the land promised to the Jews by God in the Bible, but the activity of Zionism is almost exclusively political, rather than religious, because of Jews' understanding that the land is not to be inhabited until the coming of their Messiah.

The need for a Jewish homeland began in 70 CE with the destruction of the second Temple of Jerusalem by the Romans. Since that time Jews have lived as a minority group in many countries. Despite the diversity of cultural settings and political regimes during the centuries, they have been able to maintain their ethnic, religious, and linguistic characteristics. Because of their strong nationalistic identity, they have been subjected to prejudice—known as “anti-Semitism”—and even persecution in many of the countries to which they have migrated. As a result, the primary aim of Zionists has been to find a homeland (preferably in the Jewish ancestral home of Palestine) where they can gain political independence, develop Hebrew as the spoken language, and provide a community for Jews who have been dispersed for centuries.

Writers during the nineteenth century spread Zionist ideas throughout Europe. Moses Hess wrote two works outlining the return of Jews to Palestine, *Rome and Jerusalem* (1862) and *Plan for the Colonization of the Holy Land* (1867). Leo Pinsker wrote in his pamphlet *Auto-Emancipation* (1882) that “The Jews are not a living nation; they are everywhere aliens; therefore they are despised . . . The proper and only remedy would be the creation of a Jewish nationality . . . a home of their own.”

Theodor Herzl (1860–1904), an Austrian journalist, moved to the forefront of the movement with the organization of the first Zionist Congress at Basel, Switzerland, in 1897. Delegates at the congress called for a publicly recognized Jewish home in Palestine. During the remainder of his life Herzl negotiated with world leaders to gain support for the Zionist movement. In 1903 the British government offered a large tract of land in Uganda, East Africa, for a Jewish homeland. Herzl promoted this idea to the Zionist Congress in 1903 as a “temporary haven” for Jews. Delegates at the congress strongly opposed the idea and remained committed to Palestine as the only sanctuary for Jews scattered throughout the world. Herzl died in 1904, but his contributions to the movement earned him the title of the “Father of Modern Zionism.”

Between 1881 and 1903 the first modern migration of Jews to Palestine established a small but influential presence. The first group of settlers was known as “Chovevei Zion” (Lovers of Zion). Numbering just thirteen men and one woman, the group landed at Jaffa on 7 July 1882. Many others followed during the first aliyah (going up) to Israel. In 1904 the second aliyah brought a new wave of immigrants to Palestine, mostly Russian Jews, including such influential leaders of the nation of Israel as David Ben-Gurion and Izhak Ben-Zvi. By the beginning of World War I about ninety thousand Jews were living in Palestine.

Diplomacy

Zionists pursued their political agenda for a Jewish state in Palestine through diplomatic means with Great Britain and the other Allied powers (Russia, France, England, Italy, and the United States). The

British tried to gain support in the Palestinian region from both Jews and Arabs. Because Palestine was under the political control of the Ottoman Turks, who joined Germany to oppose the Allied powers, the postwar division of Palestine by the victorious Allied forces was complicated by secret and ambiguous agreements made during the war among the British and Arabs and Jews.

Correspondence between Arab leader Sherif Hussein and the British high commissioner in Egypt, Sir Henry McMahon, expressed British support for an independent Arab state in Palestine. At the same time as these negotiations, the Sykes-Picot Agreement divided the region into mandate territories that would be under the influence or direct control of the British and French governments. The Sykes-Picot Agreement of 1916 contained provisions that contradicted the Hussein-McMahon correspondence.

Meanwhile, Chaim Weizman, a Russian-born chemist and president of the World Zionist Organization, made contacts with many British leaders to gain sympathy for the Zionist cause. David Lloyd George, prime minister of Great Britain, viewed Palestine as the biblical home of the Jews. Also, British foreign secretary Arthur Balfour was supportive of the Zionist viewpoint and hoped that a Jewish homeland in Palestine would enable the British to have an influential presence in the region. On 2 November 1917, the Balfour Declaration expressed Britain's public support for the establishment of a Jewish home in Palestine.

As a mandate territory under British control, Palestine was defined geographically for the first time in modern history. The League of Nations ratified the Palestine mandate territory in 1922. The preamble of the mandate included the Balfour Declaration, thus promoting the Zionist ideal of a Jewish state in Palestine to the status of international law.

Under British rule immigration by Jews to Palestine continued. Political and economic competition between Arabs and Jews escalated during the 1920s. Tension between the two groups climaxed in August 1929 during a Jewish religious fast when riots broke out in Jerusalem. More than sixty Jews and Arabs were killed. The British declared martial law in the region and sent an investigative commission to conduct

hearings and issue a report. The report, known as the "Passfield White Paper," stated that the riots had been caused by Arab fears of Jewish domination. The white paper called for a suspension of Jewish immigration until a policy could be created. The protest from Zionists and Jewish immigrants was so strong that the white paper was repealed the next year.

The rise of the German Nazi leader Adolph Hitler in 1933 resulted in a new wave of anti-Semitism in Europe and a large migration of Jews to Palestine. By 1936, 30 percent of the population in Palestine was Jewish. Arabs reacted violently to the migration because they feared that they would become the minority group. Arabs pleaded with the British for their support.

In 1939 the British sought to resolve the Arab-Jewish problem by limiting the Jewish population in Palestine to one-third of the total population. Furthermore, the British declared that Palestine would become an independent state within ten years. Many Zionists saw this declaration as unacceptable because the state would be under Arab majority control, and the movement to establish a Jewish homeland would end. Many Palestinian Jews demanded an immediate uprising against the British. But the most prominent Zionist group, led by David Ben-Gurion, opposed an uprising. Instead, Jews undertook active resistance to the restrictions on Jewish immigration.

During World War II Zionists supported the Allies (France, England, China, Russia, and the United States) against Germany. Zionist leaders did not become aware of the Holocaust and the German plan to annihilate the Jewish people until 1942. The war in Europe and the Holocaust made it essential for Zionists to enlist support from the United States for a Jewish state in Palestine. Prior to World War II the United States had been neutral on the issue and saw the Palestine region as the responsibility of the British government. At the Biltmore Conference of the World Zionist Organization in 1942, Zionist leaders unanimously called for the immediate establishment of a Jewish commonwealth in Palestine and sought to pressure the United States into supporting their agenda. However, both British and U.S. governments opposed the Zionist plan because they wanted to

maintain close ties with Arab neighbors who controlled vital oil deposits.

U.N. Resolution 181

At the end of World War II the British government sought an end to the mounting violence between Jews and Arabs in Palestine. Unable to mediate a settlement, the British unceremoniously turned the problem over to the United Nations in 1947. After much deliberation the United Nations on 29 November 1947 passed Resolution 181, which proposed partition of Palestine into separate Arab and Jewish states, with Jerusalem under permanent trusteeship. This resolution guaranteed a Jewish homeland. The Arabs immediately opposed the partition with violence. British troops hastily left the region in May 1948, refusing to enforce the U.N. resolution, and Zionists proclaimed the creation of the state of Israel. The first Arab–Israeli war erupted on 15 May 1948, with Arab armies from Egypt, Lebanon, Syria, and Iraq invading Israel. After a series of ceasefires and armistice agreements, Israel won its independence, and the Zionist dream was a reality.

Since the establishment of Israel as a state, Zionism has continued, offering a homeland to Jews who embrace Israel as theirs. Formalized support also continues as Zionists create economic and political programs that support their cause and as they continue to remind Israel that their definition as a state also delineates their culture and history as Jews. The most activist sects of the Zionist movement have viewed the military successes of Israel in the 1948 War of Independence and the Six-Day War of 1967 as divine miracles and a foreshadowing of the coming of the biblical Messiah. Thus, some Zionists view the retaining of the biblical land of Israel as a “holy war” against Palestinian nationalist ideologies and Islamic religious movements. Furthermore, they believe that the existence of Palestinian settlements in the West Bank and Gaza Strip has prevented Jews from being able to claim complete or at least peaceful success in their goal of a homeland. More moderate Zionists have maintained a purely political agenda to continue to secure a homeland for Jews and maintain a cultural

identity, trying to live in peace with their neighbors. However, some countries outside of the Middle East strongly believe that Zionism has refined itself from what had begun as a political agenda to an agenda driven by religious ideology.

To gain influence with the Arab community, Russia influenced the United Nations to draft Resolution 3379 on 10 November 1975, condemning Zionism as a form of racism and racial discrimination. The United States and its Western allies, who saw the resolution as a condemnation of the nation of Israel, bitterly contested the resolution. In 1991 the resolution was repealed amid efforts to allow the United Nations to play a role in the ongoing Middle East peace talks.

Zionism continues to play a major role in the Middle East peace talks as recent terrorist attacks have led to a call for more national unity in Israel in the spirit of the early days of the movement. Zionist rhetoric is used by both Jews and Arabs to describe the tense political situation in the region. The key to the future of Zionism is the connection between its religious identity and its desire for a homeland.

Zoroastrianism

Zoroaster was a Persian prophet who taught that rival gods—one good, one evil—struggled for control of the world. He called on his followers to support the good and promised them eternal life after the fiery end of the world. Today about two hundred thousand Zoroastrians remain in Iran, India, and North America. Zoroastrian dualism survives in concepts of hell and the devil as formulated in the Christian and Muslim religions.

Zoroastrianism is the ancient religion of the Iranian people. The prophet of this religion is Zarathushtra (Greek form Zoroaster), who lived approximately 1000 BCE in eastern Persia. The religion of the Iranians was closely related to that of the Indians who had immigrated to the Indus region. The Indo-Iranian religion was polytheistic and included two groups of deities, the Ahuras and the Daivas. Zoroaster reformed the old Indo-Iranian religion and made one group of these deities the beneficent ones (Ahuras), and another maleficent (Daivas). Among the Ahuras, one named Ahura Mazda (Wise Lord) was made supreme and the creator of the world and all that is good. Ahura Mazda was aided by a group of deities who act as his aspects or his archangels. While they were not a fixed number during the time of the prophet, they include Khshathra (Dominion); Haurvatat (Health); Spenta Armaiti (Devotion); Ameretat (Immortality); Vohu Manah (Good Thought); Asha (Truth/Order); and Spenta Mainyu (Holy Spirit).

Ahura Mazda is opposed by a host of fallen deities, the Daivas, who remained supreme in the Indic religion. For of each of Ahura Mazda archangels a deadly

and maleficent demon was created to bring death and destruction to the world. These Daivas are headed by Angra Mainyu (Ahriman), which can be translated as Evil Spirit. It is the Daivas who attempt to destabilize the universal order (arta) and are in constant battle with the Ahuras. According to Zoroaster's own words, people have the freedom of will to choose with a clear mind between the two sides, but if one chooses to be on the side of the Daivas and Angra Mainyu, he or she will suffer at the time of renovation (end of time) and will be placed in the Zoroastrian hell, which is dark and full of stench. But if one chooses on the side of Ahura Mazda, he or she will be prosperous and at the end of time will remain in the house of songs and best existence, that is, heaven. This is the first time in history that we find these concepts set forth, which later influenced Abrahamic religions when the Achaemenid Persian Empire ruled over Asia and the eastern Mediterranean.

The prophecies of Zoroaster are contained in seventeen hymns known as the Gathas of Zoroaster, which are part of a greater collection of hymns written down in the Sasanian period in the sixth century CE, known as the Avesta. The Avesta is multilayered and parts of it can be dated to different periods of Persian history. When Zoroaster passed away, his community composed a series of seven hymns known as Yasna Haptanhaiti, which is a further blessing of the Ahuras and solidification of Zoroastrian beliefs. By the time of the Achaemenid Persian Empire, the old Ahuras and some of the Indo-Iranian deities who were not the focus of Zoroaster's devotion made their appearance in the Zoroastrian religion. A number of deities such as Anahita, Mithra, Verethragna, Sraosha, and Tishtarya are worshiped and mentioned

Let us be such as help the life of the future. • **Zoroaster (c. 1000 BCE)**

in the part of the Avesta known as the Yashts. These Yashts are hymns to various deities who are invoked for specific purposes and have various functions and associations.

For example, Anahita is associated with water and fertility, Mithra with oaths and later the sun, and Verethragna with offensive victory. The section of the Avesta that mainly deals with law of purity and pollution as well as early myths of the Iranian people is known as Widewdad (antidemonic law).

The priests who memorized these sacred words and were responsible for the compilation of all the hymns are known as the Magi. They appear to have been a Median tribe (according to Herodotus) who were specialists in religion and served from the time of the Achaemenid period onward. One of the ceremonies of the Magi was the Haoma ceremony, in which the Magus mixed plant juice with milk and drank it in order to gain power and have visions. Fire is the other sacred element, which the Magi respected and before which they sang hymns. Hence, the place where the sacred fire burned and the place where the Magi worshiped was known as the fire-temple.

By the Sasanian Persian Empire in the third century CE, the hymns that were memorized were collected and those that were deemed unfit were forsaken. The Sasanian state became allied with the Zoroastrian Magi and a Zoroastrian Empire was born. The

In the Zoroastrian pantheon Ahura Mazda (Wise Lord) is the supreme deity and the beneficent creator of the world.

Avesta was codified and written down in a specific script. With the Arab Muslim conquest of Persia in the seventh century CE, the number of Zoroastrians began to dwindle. The Zoroastrians became a minority in the

Muslim Empire and while some remained in Persia, many left for India. Today about two hundred thousand Zoroastrians remain in the world, mainly in Iran, India, and North America. Because of the low birth rate and the fact that Zoroastrianism is not a proselytizing religion, the number of followers of this religion is dwindling.
